

sequent studies of a similar nature have been undertaken by a number of medical societies and city, county, and state health departments in their own localities, using the same schedule that was devised for the larger study. The White House Conference on Child Health and Protection has published a committee report containing a frank account of the failings of obstetric education in this country and recommendations for its improvement. Large attendance is reported at graduate courses in obstetrics which have been offered to physicians by state boards of health and county medical societies in a number of places. State boards of health have continued their efforts to train midwives in places where the midwife still exists. . . .

The fact that during the period 1921 to 1929 there was a significant downward tendency of about 2 per cent a year in the deaths due to albuminuria and convulsions, which may largely be prevented by prenatal care, would seem to indicate that popular education in this respect is bringing results. Recent surveys show, however, that even now the great majority of women do not receive such care, and it is of great importance that facilities for education in maternal health should be increased. . . .

The Children's Bureau has three projects for promoting uniform reporting of statistics relating to children and child welfare. In 1920 it began to assemble and analyze reports on the issuance of work permits as a means

of providing current information regarding the number of children receiving official permission to leave school for work. In 1927 it began to assemble reports from juvenile courts and to work out with the courts uniform practices in defining and recording cases, so that comparable delinquency trends would be available. Finally, in 1930, it took over the project for current reporting in selected metropolitan areas in some 22 fields.

The closing statement of this illuminating report should be taken seriously to heart by everyone interested in the welfare of the child.

Child welfare workers everywhere look to the coming year with much anxiety. It will take great effort to maintain the standards of service for children which were slowly developed during the years before the depression, to make sure that their interests are safeguarded in the general economies which the depression has made necessary. Neglect of the health, education, and general welfare of children will be permanently costly to the children and to the future of the country.—

Twentieth Annual Report of The Chief of The Children's Bureau to the Secretary of Labor, Fiscal year ended June 30, 1932. United States Government Printing Office, Washington, 1932.

PUBLIC HEALTH NURSING*

Twenty Years of Red Cross Public Health Nursing—In 1910 Lillian Wald, R.N., who was responsible for the establishment of the Henry Street nursing service and the school nursing service in New York City, wrote Jacob Schiff, one of the farseeing members of the Board of Incorporators of the American Red Cross, thus:

In the older countries armies of trained nurses are sent into remote country regions to nurse, to educate, to bring scientific, advanced humanitarian and sanitary messages to the public. In America, in a few sporadic instances only, are nursing care and protection against infection possible to the sick

country person. . . . Why should not the Red Cross Society undertake the organization of a vast, far-reaching scheme of country nursing, getting such support and coöperation as may be possible from the dwellers in mountain, farming or lonely desert regions, coördinating and guiding all, and bringing the help of the nurse to scattered, isolated families? . . . There could be no larger or nobler work possible to the Red Cross Society of a country dedicated to peace.

This letter was presented at the annual meeting of the Red Cross, but no action was taken until the annual meeting the following year when Mr. Schiff offered \$100,000 to start the enterprise and Mrs. Whitelaw Reid offered \$10,000 for scholarships to prepare nurses for rural nursing. A trial year was agreed upon and was so successful that in 1913

THE NATION'S HEALTH

failing and the continuation of many rural public health nursing services is in danger these nonofficial agencies are again filling the breach until they can again be officially resumed. E. F. M.

Why Not Make Use of the N.O.P.H.N.? — Katharine Tucker, R.N., general director of the National Organization for Public Health Nursing, who was appointed a member of the New York State Health Commission by Governor Roosevelt, has been appointed consultant in public health nursing to the State Department of Health.—*Health News*, New York State Dept. of Health, IX, 44:179 (Oct.), 1932.

To anyone who knows how haphazardly public health nursing started and is being carried on in many state health departments, the arrangement made between the New York State Health Department and Miss Tucker will have a strong appeal. Let us hope that it will set a precedent for other states to follow.

As a Private Physician Sees Us— If one physician asks another what he thinks of public health nursing he is apt to be greeted with a stare that asks "Now what are you about to start?" Then he probably replies that he knows very little about it. Sometimes he may remember a personal experience with a nurse when she was believed to have done such and such and said so and so.

In Toronto a physician thinks of a public health nurse as one who spends her time in teaching rather than in nursing. Members of the Victorian Order or the St. Elizabeth Order do not usually occur to him as being public health nurses. He does not know how the teaching nurse spends her day, and what he hears about her comes to him second hand. She is a member of a group; he is on his own. He fears her because he does not know her and because she appears less as an indi-

vidual than a group member. If he could only know her as an individual his apprehension about her activities would probably fade away.

A nurse can make no better contact with a physician than to be present at a confinement in a private home. Yet very few public health nurses are in delivery service. It is very seldom that the nurse who gives prenatal supervision to a patient does the actual obstetrical nursing also. There may be another nurse who does the follow-up infant welfare work. The continuity of favorable relations between one physician and one nurse is broken and the arrangement makes the physician seem unimportant.

It is astonishing how long a doctor remembers an indiscretion of a public health nurse. It makes him twice shy of her. Every doctor should be asked to report any indiscretions on the part of nurses to their organization so that misunderstandings could be adjusted at the beginning.

It would be good for the doctor to know of the nurse's constant attempt to refer his patients to him, keeping herself in the background; it would help a great deal if he could know what the nurse is able to do for him. He already makes use of the public health laboratory; he should make equally good use of the public health nurse in getting her to see that the families he is attending carry out his instructions. But how can he be assured that she will not give advice to his patients without his expressed desire unless he knows her well enough to trust her?

The doctor gets a long distance view of public health nurses busying themselves with what appear to him as trivialities. For much of this work he cannot see the need of a nurse's training.

A doctor's survival in his profession depends on whether his advice is accepted, the public health nurse's does not. In her zeal to help a family in-

EDUCATION AND PUBLICITY*

In Magazines and Books—We would like to record books and magazine articles about health and health workers. Please tell the editor when you discover anything, either sympathetic or otherwise.

"The Nurse in Current Fiction" reviews four books: "Hospital," by Truax; "District Nurse," by Baldwin; "Miss Pinkerton," by Rinehart; "The Affair at Tideways," by Heath. *Trained Nurse*. Aug., 1932.

A Publicity Council In Your City?—Sixteen cities have social work publicity councils. Health workers are prominent in most of them. Why not a health education group in every one of them? Health workers have much to gain from general discussions of interpretation, education or publicity. Also there is much to gain in small groups getting together to study health education as such. Where the chest or council of social agencies has not formed a publicity group those interested in health publicity and education might bring it about. Plans for such groups will be supplied by Social Work Publicity Council, 130 East 22d St., New York.

Posters From Far and Near—Through the courtesy of League of Red Cross Societies and other health agencies, several years ago *Hygia* reproduced in miniature some of the world's best health posters. Only recently did we learn that those reproductions are available on a set of sheets, 8½" x 11½", at 25 cents. Address *Hygia*, 535 North Dearborn

St., Chicago. While much reduced in size, the original brilliant colors are preserved. The 44 posters came from Bahia, France, Germany, China, Lithuania, Russia, India, Japan, and Latvia. The posters from India and Russia deal with prenatal care, but the remainder are suitable for home and school use. Children will delight in studying the Chinese poster lesson in hygienic eating with chopsticks, and the colorful Japanese posters on swatting the fly and brushing the teeth. The happy French posters on bathing and outdoor sports, the German mother, the Lithuanian "little mother," and the grotesqueries from far-off Bahia will appeal to the children.

What to Tell About Public Health—The freshest collection of quotable and usable material is contained in the series entitled "Behind the Front Lines," issued by Association of Community Chests and Councils, Graybar Building, New York. Subjects: "Child Health," "Hospitals," "Mental Hygiene," "Public Health Nursing," "Social Hygiene," "Tuberculosis." Write your national, or send 10 cents a copy for any of these bulletins.

The "Smithson Family" In Connecticut—The summer experiences of the "Smithson family" were revealed by radio last July, August and September. The State Department of Health caught them via the microphone for 5 minutes every Wednesday according to the following schedule:

The family is discussing vacation.

They enjoy a picnic lunch.

They take Aunt Adelaide who does nothing but talk about her grandchildren. A. Elizabeth Ingraham, M.D. (as Aunt Adelaide).

They stop for advice at health officer's

in flow of only 0.24 per cent per centigrade degree of temperature. This would be of no consequence within the range of temperature under which the device would be operated.

It was first thought that calcium from the hypochlorite solution would deposit on the inside of the capillary tubing. In such an event it was planned to instruct the operator to replace the tube frequently and soak the used tube in vinegar (or acetic acid) over night and then flush it with water. Experience has shown that there is little or no tendency for deposits to collect on the inner surface of the tubes, even where the hypochlorite is made locally from the high test powdered products. Apparently a scouring velocity occurs in the tube. In one installation using 18" of 3/4 mm. capillary tubing and in another using 12" of 1 mm. tubing, replacements were made only after daily use over periods of 6 and 8 months respectively.

Although the above indicates that the deposition of calcium is not a factor, it is advisable to make the stock solution of hypochlorite as clear as practical, to

use a clear water in preparing and diluting the hypochlorite and to replace the capillary tubing at regular intervals, such as once a week or once a month. The tubes cost but \$.20 each; so therefore breakage in handling is of no importance.

THE EXTENT OF USE

This device, in one or the other form, has been in use by the federal government on one installation during a period of more than 2 years, on another installation during a period of over 1 year, and on two other installations during a period of over 6 months. Four installations were recently made at Indian Emergency Conservation Camps and the equipment has been purchased for four additional installations by federal officials who were convinced of the practical application of the device through observation of the earlier installations.

The rate of flow treated in these cases ranges from 4 gal. to 60 gal. per minute. The device is not particularly limited to low rates of flow. By feeding undiluted 14.5 per cent hypo-

KIMBLE'S NEW  BLUE LINE

RETEMPERED— for Assured Strength

THE new Kimble Exax Blue Line of Graduated Glassware not only excels in fine appearance, but is outstanding in its durability and constructional strength. Every piece receives the exclusive Kimble

re-annealing treatment—a re-tempering process, in a special lehr or oven, that removes all strains, and insures against weak spots and excessive breakage.

The blue calibration lines and numerals—formed by real glass enamel actually fused into the glassware—make the new Kimble Exax Line decidedly more practical and easier to read than any other scientific glassware.

Standardize on Blue Exax—for service, durability, economy and assured accuracy. It is Kimble-made and Kimble-guaranteed. Available at all leading Laboratory Supply Houses throughout the United States and Canada.

FIGURE I

Camera Lucida tracings of silicotic nodules at various intervals of exposure. The nodules from the ordinary case of silicosis are larger than the entire area of this figure.

the nodules encountered in any lung are quite uniform in size and that small, apparently fresh nodules are relatively rare after prolonged exposures.

In the cases under discussion the nodules are massed in a compact zone, a centimeter or more in width, beneath the pleura. Along many of the interlobular septa there are wide bands of closely packed nodules which encroach upon the parenchyma on either side. In such formations the lesions are surrounded and embedded in sheets of loose cellular or hyaline connective tissue containing appreciable quantities of fine black dust particles. A few nodules also occur singly or in small clusters throughout the alveolar tissue. When stained by Foot's method for reticulum, the impression is gained that the reaction is relatively young, for black staining reticulum predominates over red stained collagenous elements. In many air spaces are masses of necrotic exudate which may be produced by the action of silica. The polarizing microscope reveals excessive amounts of exceedingly fine, doubly refractile particles with

relatively few of the large acicular and needle-like fragments which are so common in the ordinary silicotic lesions. In the case of the 2 white tunnel workers who admitted having had 4 to 7 years previous employment in coal mines, the silicotic nodules are 4 or 5 times as large and frequently occur as aggregations surrounded by a capsule of cellular connective tissue.

In all cases the interalveolar septa are generally thickened. In the presence of chronic infection it is impossible to estimate how much of this change is due to the silica, but when the infection is acute and exudative it probably has little effect upon the pulmonary framework. The bronchial lymph nodes were available for examination in 13 of the cases, and among these only 61 per cent showed definite silicotic nodules. In each instance at least 3 different nodes were examined.

In all of the cases death was due to pulmonary infection; in 11 this was definitely tuberculous; in 2 there was an acute and chronic non-tuberculous pneumonia, and in the other 3, tuber-

Reprint prices furnished upon request

During periods of use, swimming pool water showed marked pollution as measured by colon bacilli and streptococci indices in the presence of residual chlorine contents of 0.2 to 0.5 p.p.m. . . .

A sodium thiosulphate treated sample bottle was recommended for collecting pool samples.

Because of the several advantages to be gained in using chloramines over the use of chlorine alone, and because of the above conclusions, it was decided to carry on the following studies relative to the use of chlorine and ammonia in connection with the routine control of all swimming pools during the months of June, July, and August, 1933.

1. Collect duplicate samples for every sample taken this season during times of swimming—one sample to be handled in the usual manner and tested after the inspector reaches the laboratory and the other sample collected in sodium-thio-sulphate treated bottles.

2. Run several laboratory tests to determine if sodium thio-sulphate treated bottles had any disinfecting effect on samples collected between the time of collection and the time of delivery at the laboratory.

3. Check at intervals the increase in the free ammonia content at those pools using chlorine and ammonia treatment where the water was recirculated and not completely drained in several weeks or longer.

4. The control of slime or algal growths on the bottom and sides of pools by using:

- a. An increased dose of chlorine.
- b. By the use of copper sulphate.

DETAILS OF THE STUDIES

Study 1. Comparison of Samples Collected and Tested in the Usual Manner and Those Collected in Sodium Thio-sulphate Treated Bottles—

Two duplicate samples were collected twice a week from each pool. Two samples at each inspection collected and handled in the usual manner and tested after reaching the laboratory and two other samples collected in sodium thio-sulphate treated bottles.

In the selection of a dechlorinating agent, the following chemicals were considered: sodium thiosulphate, sodium

bisulphite, and sodium sulphite. Sodium metasilphite (which had been recommended to us by Dr. Schmelkes), was not obtainable on the market except as a special order in large quantities (J. T. Baker Chemical Co., Phillipsburg, N. J.). Of the three substances considered as antichlors, sodium thiosulphate seemed to be the most satisfactory for routine purposes. Both sodium bisulphite and sodium sulphite decomposed under steam sterilization and lost practically all of their dechlorinating power, a difficulty which was not encountered with the thiosulphate. While either the bisulphite or the sulphite could no doubt have been used under special conditions of preparation, for the purposes of routine use, the thio-sulphate offered distinct advantages.

PREPARATION OF THIOSULPHATE

TREATED SAMPLE BOTTLES

Ordinary 4 oz. wide mouth bottles with tinfoil covered corks and hood of heavier lead foil were used for collection of samples. The bottles were sterilized as usual in the hot air oven; 1.5 gm. of crystallized sodium thio-sulphate were dissolved in a liter of sterile water and 1 c.c. of the solution added to each bottle; the bottles were then autoclaved for 5 min. at 15 lb. steam pressure. Bottles were freshly prepared for periods not exceeding 2 or 3 days but the stock solution of sodium thiosulphate was used over a longer period of time.

Chart 1 represents the results of 42 samples collected from 2 swimming pools where chlorine was used alone without the addition of ammonia. Average bacteria counts are plotted as the abscissa and the chlorine residuals as the ordinate. These studies showed that at a residual of 0.1 p.p.m., the average count was 6 and no single sample was above 12. Forty-two portions were run for *B. coli* content and all were negative. Chart 2 represents the re-

Making the telephone MORE VALUABLE to more people

The constant purpose of the Bell System is to make the telephone worth more and more to all who use it. To that end eight helpful ways to increase the usefulness of the telephone in your home or office are listed below. . . . Some of these you may know. Others may come as a welcome surprise—as something you often have wished for without knowing it is so readily available.

Extension Telephones. A great convenience in bedroom, kitchen and living-room. Make stair climbing unnecessary. Improve business efficiency in the office. Save many steps every day.

Hand Telephones. Modern. Distinctive in appearance. An attractive addition to any room. Leave one hand free to take notes while telephoning.

Portable Telephones. Plug in the wall like a lamp. May be moved from one room to another as needed.

Individual Lines. Cost little more than party line service. Assure additional privacy. Your line is "busy" only when you use it.

Intercommunicating Facilities. Provide for making calls from one part of the home or office to another or transferring of incoming calls without the aid of the central office operator. Save time and steps and lead to a quiet, smooth-running establishment.

Additional Bell Signals. For use in noisy locations or where it is necessary to summon people from a distance to answer the telephone.

Additional Directory Listings. Enable friends to locate you even though the telephone is in the name of husband, brother or sister, or another relative. In addition to the firm's name, your own can be shown. Direct business to you. The cost is small.

Telephone Planning. The telephone company in your city will gladly assist you in planning the most convenient telephone facilities for your home or office. The services of telephone experts are at your disposal.

Call the Business Office of your Bell Telephone Company for full information about any of the services listed above.

AMERICAN TELEPHONE AND TELEGRAPH COMPANY

free ammonia tests were made on this date for this pool, but based on the results of a number of such tests made on several pools during this summer, it seems reasonable to assume that the free ammonia content was not over 1 p.p.m.

No pH tests were made on this pool on or near this date. Forty-five routine tests for pH were made during the summer of 1932 and these averaged 7.6, with a minimum of 7.3 and a maximum of 8.2. After checking the probable pH and free ammonia content of the pool on this day, it was decided that the water probably had a normal pH and free ammonia content.

The portion which showed positive for *B. coli* at 0.5 residual was collected from an outdoor pool on August 18 at 3:30 P.M. The counts for the dechlorinated samples were 40 and 8 with 1 portion positive for *B. coli* and 1 portion negative. The counts for the ordinary samples were 18 and 5 with both portions negative for *B. coli*. Unfortunately the records kept do not show the last date that the pool was drained previous to the collection of these 2 samples, nor did they show the pH of the pool water nor the free ammonia content. A free ammonia test on August 23 at this pool showed 1.04 p.p.m.

Study 2. Laboratory Tests to Determine If Sodium Thiosulphate Treated Bottles Had Any Disinfecting Effect on Samples Collected—

The amount of sodium thiosulphate used was found to be sufficient to dechlorinate 100 c.c. of water immediately and completely, in which the residual chlorine, as determined by the orthotolidin test varied from 0 to 1.5 p.p.m. of residual chlorine. There was always a considerable excess of thiosulphate present after dechlorination was complete. Experimentally the amount of sodium thiosulphate was sufficient to

dechlorinate 100 c.c. of water or the capacity of the 4 oz. collecting bottle containing approximating 3.5 p.p.m. of residual chlorine.

With an excess of sodium thiosulphate present and the several products of the reaction involved in the dechlorination process, which probably include sodium tetrathionate, sodium sulphate, and sodium chloride, the question naturally arose regarding the possibility of sterilization or temporary inhibition of bacterial life in the dechlorinated samples. In an effort to determine whether or not the dechlorinating action or any of the end-products formed exerted a sterilizing effect, the following checks were made:

Approximately equal suspensions of bacteria recovered from water were inoculated into (1) 100 c.c. of sterile water; (2) 99 c.c. of sterile water to which was added 1 c.c. of a solution of sodium thiosulphate containing 1.5 gm. of crystallized salt per liter; and (3) and (4) duplicate samples of 49 c.c. each of sterile water to which were added 1 c.c. of sodium thiosulphate as above, and 50 c.c. of a solution containing residual chlorine in the amount of 2 p.p.m. Plates were made from the series of 4 samples at various times and for several series containing different numbers of organisms. (Results are shown in Table I.)

From the results obtained it would appear that little effect is exerted on the bacteria present and that probably the dechlorinated samples represent approximately the condition of the pool water at time of collection. (It is hoped that during the coming season conditions will permit the establishment of a portable laboratory at the municipal pool for actually checking this point.)

samples were collected twice a week from this pool, none of the portions tested for *B. coli* were positive. The pool was drained and refilled, and normal operations resulted. There is a possibility, of course, that the inspector, not realizing that the free ammonia content was so high, failed to wait long enough for the color to appear, inasmuch as the free ammonia would undoubtedly slow up the color reaction considerably.

Tests were made for free ammonia on the Municipal Fair Frounds Pool and it is interesting to note that after the pool had been operating for 3 days, after filling with clean water, the free ammonia showed, for one of the tests 0.48 p.p.m., and at another time 0.52 p.p.m. Nine days after the pool had been refilled with fresh water, the free ammonia content was 1.2 p.p.m., and 11 days after it showed 1 p.p.m. (See Table II.) This pool is one of those that was emptied every 2 weeks because of the temperature of the water. The ratio of ammonia to chlorine at this pool averaged approximately 1 to 3 for the months of July and August. Instructions were issued to all pools to dose with a 1 to 4 ratio of ammonia to chlorine for a few days after refilling and then cut to 1 to 10.

were made at the Fair Grounds Pool. This is a 1,125,000 gal., oval shaped pool with the deep water in the center, with a depth of about 3" or 4" all the way around at the outer edge and 10' in the center. The inlets are spaced about 50' apart all around and the turnover is approximately 48 hours. Several attempts to control algae by increasing the chlorine residual in the pool at night were unsuccessful due to the slow rate of recirculation and the necessary waste of water and addition of new city water in order to bring the residual back to below 1 p.p.m. within a few hours.

We quote from a paper read last year before this section regarding the effect of algal growth in using up the chlorine to the point of making it difficult to maintain a residual:

It was also observed that an increase of the use of copper sulphate up to approximately 3.5 to 4 p.p.m. applied every third day, tended to reduce the chlorine demand, presumably by more effective control of algae.

While this dose of 4 p.p.m., or about $3\frac{1}{2}$ lb. to 100,000 gal. reduced the chlorine demand, the dose was not strong enough or the application frequent enough to prevent the growth. The dose of copper sulphate was therefore increased and the frequency of ap-

TABLE II

Study 4. The Control of Algae With Copper Sulphate—

The studies made on the control of slime or algae by increasing the chlorine residual of the swimming pool

plication was increased until finally the growth of the slime or algae on the bottom of the pool had been completely and definitely prevented by using a 5 lb. to 100,000 gal. dose the last thing

Its* importance in *Furunculosis* has been recognized for 75 years

More than three-quarters of a century ago one of the first scientific reports on the therapeutic value of yeast appeared in the columns of the London Lancet. It covered a series of cases of boils.

The treatment of furunculosis with fresh yeast is a very widely accepted practice today among dermatologists and general practitioners, and the results are such as amply to justify it. Recently, it has been shown that fresh yeast has the ability to increase very noticeably the so-called "self-disinfecting" power of the skin.

Thus the value of fresh yeast in skin disorders is due only partially to its laxative action — just as its effect in

digestive disorders is likewise due to a combination of nutritional and therapeutic effects.

* Fleischmann's fresh Yeast is the only yeast containing 3 vitamins—B, G, D.

Recommend 3 cakes daily—plain or dissolved in a third of a glass of water.

Hemolytic Properties of the Mastitis Streptococcus*

P. ARNE HANSEN, G. J. HUCKER, PH.D., AND
MARION A. SNYDER

New York State Agricultural Experiment Station, Geneva, N. Y.

BLOOD agar plates have gained wide use in the identification of bacteria, especially in the case of streptococci. Introduced by Marmorek (1902) and later, studied more in detail by Schottmüller (1903), the use of blood agar has come to be a useful procedure in identifying streptococci. Brown (1919) described in detail the various types of colonies produced on solid blood agar and emphasized the importance of using standard procedures and a standard means of designation. He divided the various types of colonies into groups, viz., alpha, alpha prime, beta and gamma, these terms to apply only to deep colonies. The alpha type produces green coloration of the medium surrounding the colonies. Under low power magnification faint hemolysis may be noted in the outer portions of the zone. When a plate seeded with alpha hemolytic colonies is placed in the refrigerator after previous incubation of 48 hours at 37° C., an outer hemolytic zone will be noticed. The alpha prime type colony is intermediate between the alpha and the beta types. The colony is surrounded by a hemolyzed zone. This zone, however, is not clear and may, when viewed under low power magnifica-

tion, be seen to contain the red blood corpuscles in a fixed condition. The surface colony should not be used in the classification as it may be indistinguishable from the beta type.

The beta type is characterized by the surrounding halo which is perfectly clear. No red blood corpuscles may be seen in this clear zone even when examined microscopically by magnification. The gamma type is produced by organisms which do not produce hemolysis or decolorize the blood medium. Brown calls both the alpha prime and the beta type, "hemolytic," yet the former is considered more closely related to the alpha than to the beta type.

The blood agar plate has been used widely in the case of the mastitis streptococcus. By a study of the literature it may be noted that no agreement is found regarding the hemolytic powers of this streptococcus. The typical streptococcus of mastitis (*Streptococcus mastitidis*) † is as a rule described as being alpha or gamma hemolytic, but not infrequently reports are found designating it as beta hemolytic.

Gminder (1912) tested 26 udder streptococci on the blood plate prepared

* Read before the Laboratory Section of the American Public Health Association at the Sixty-second Annual Meeting in Indianapolis, Ind., October 12, 1933.

Approved by the Director of the New York State Agricultural Experiment Station as *Journal Paper* No. 8.

† In this discussion the term *Streptococcus mastitidis* Migula will be used to designate the streptococcus associated with chronic or subclinical mastitis. The nomenclature of this organism will be subsequently determined. The use of this terminology at this time should not be construed to infer that the authors prefer this name to *Streptococcus agalactiae* Lehmann and Neumann.

tidis and the possible significance of this characteristic in the detection of udder infections.

TECHNIC

Freshly grown cultures were plated in the various media and examined after 48 hours' incubation at 37° C. The plates were then placed in the refrigerator, chilled for another 48 hours, and examined again. The media used were: (1) horse blood agar, prepared from fermented veal broth, (2) horse blood agar, prepared from plain veal broth, (3) horse blood agar, prepared from plain veal broth plus 0.05 per cent glucose, (4) sheep blood agar, prepared from plain veal broth plus 0.05 per cent glucose, (5) cow blood agar prepared from plain veal broth. The broth which constituted the basic part of all the media had the following composition:

| | |
|------------------------------------|------------|
| Veal infusion from 500 g. veal.... | 1,000 c.c. |
| Bacto peptone | 10 g. |
| NaCl | 5 g. |
| Agar | 15 g. |
| Reaction adjusted to pH 7.4 | |

The media were tubed in 12 c.c. lots and 0.6 c.c. of blood was added before use. The blood was always left at least 48 hours in the cold before being used for plating.

To supplement the results as secured with the blood agar plates, tests for hemolysin production were carried out in liquid media. One-half c.c. of an 18 hour culture in sugar-free broth was placed in a small test tube and 0.5 c.c. of 5 per cent washed suspension of sheep cells was added. The tubes were kept at 37° C. in a water bath and examined at regular intervals: 20 min., 1 hour, and 3 hours.

DISCUSSION

It is apparent (Table I) from a study of recognized strains of *S. mastitidis* that the majority are alpha hemolytic and a lesser number alpha prime, bordering on weak beta hemolysis.

Distinct and vigorous beta hemolysis was never observed, regardless of the kind of blood or the presence or absence of glucose. This observation is especially significant when it is realized that some workers report that the same strain varies in different laboratories from alpha to strong beta hemolytic.

The types beta, alpha, alpha prime, and gamma may not represent distinct types in all cases and further study is needed to decide on the mechanism of hemolysis in the weak beta hemolytic strains. Hemolysis is a complicated process depending on many factors of which not all are fully understood. The quantitative importance of these various factors has never been worked out; productions of true hemolysins, of acid and of peroxide. It is probable that the various types of hemolysis for the time being should only be considered as rough descriptions which should be confirmed by quantitative measurements.

While it may be difficult or impossible to distinguish between the various types, the difficulty, frequently described, that a certain strain varies greatly from time to time when tested on blood plates has not been encountered. Different transfers of the same strain kept for years in different culture collections under varied conditions gave identical results. Many examples of this type are found in these data (see 1 and 17, 3 and 8, 6 and 9, etc. Table I).

Brown (1919) suggested that glucose even in small amount had a marked effect on the degree of hemolysis of colonies on blood plates. That the hemolysis is somewhat suppressed by the addition of glucose becomes especially important in the case of probable intermediate types. In a medium containing glucose certain strains (No. 49) may resemble the alpha prime type while in a sugar free medium the hemolysis is so pronounced

« « **ANNOUNCING** » »

A New Edition of
STANDARD METHODS
 for the Examination of
WATER and SEWAGE

Prepared under the joint auspices of the
 AMERICAN PUBLIC HEALTH ASSOCIATION
and the
 AMERICAN WATER WORKS ASSOCIATION

- This announcement is of the utmost significance to sanitarians, engineers, bacteriologists, chemists and others concerned with the establishment and maintenance of pure water supplies.
- The previous edition of Standard Methods is dated 1925. In the new edition, the Seventh, many important additions and changes occur. As examples:

The method for total hardness has been extensively revised
 The ortho-tolidine test for chlorine is presented more exactly
 The determination of the biochemical oxygen demand has been rewritten
 The use of brilliant green lactose peptone bile is allowed in conjunction with standard lactose broth for water purification plant control
 The recommended drinking water standards of the U.S.P.H.S. are included
 Twenty-three methods of analysis which are not yet recommended as standard procedures, but which may be of use, are presented in abstract and with references

- The New Edition of Standard Methods for the Examination of Water and Sewage is urgently recommended for use in water works and public health laboratories, in place of the obsolescent 1925 volume, by the American Public Health Association and the American Water Works Association. Its price is \$2.00.

Order from
The American Public Health Association
 450 Seventh Avenue New York, N. Y.

MOTHERS' MILK

normally does not contain sufficient Vitamin D

SO much evidence has been adduced on this point that physicians now very generally recognize the need for a way to supplement the lack of anti-rachitic vitamin D in the diet of the nursing child.

Yet the direct administration of vitamin D to very young infants has obvious disadvantages.

It is for this reason that a means of increasing the vitamin D potency of mothers' milk itself has been sought by research workers. And preliminary tests among groups of lactating mothers now indicate that an excellent transfer of this vitamin from the diet to mothers' milk *is obtained when Fleischmann's*

Yeast is added to the diet.

Every cake of Fleischmann's Yeast is now "irradiated" with ultra-violet rays. Every cake has a known vitamin D potency . . . greater than that of any other food. And in addition, it is of course extremely rich in vitamins B and G, also essential in the diet, particularly during lactation and pregnancy.

Only *Fleischmann's* fresh Yeast, you know, contains all three of these vitamins, B, G and D, together with all yeast's other natural nutritional and therapeutic elements.

Simply recommend three cakes daily—plain, or in water, milk or fruit juice.

It is the richest food in Vitamin D...

Without these facts, you wouldn't believe this

Thousands of children all over America drink coffee daily!

IN SPITE of the years of educational work carried on by physicians, public health officials and such societies as the American Child Health Association, surveys show that an alarming number of school children are given coffee each day.

Over 50% Drink Coffee

For example, a recent survey in and around Pittsburgh shows that 56.6% (1,264 out of 2,231) of the children of school age drink coffee. In San Francisco out of 15,000 grammar school children over half that number were found to drink coffee.

Another survey, conducted among 80,000 school children by a world famous Research Institution shows that youngsters who drink coffee stand far less chance of good grades than those who don't. And even if other causes, besides the caffeine habit, contributed to their backwardness, the fact remains that coffee drinking children are not as good at their studies as those who do not drink it.

Coffee Robs Children of Milk

Furthermore the Research Institution found

that coffee drinking is frequently a cause of malnutrition—children who drink coffee are apt to drink too little milk.

Thousands of fathers and mothers have become so used to coffee that they have failed to realize the harm it can do to their children. Many parents make the excuse—"My children need a hot drink in the morning." Of course they do. But why one that tears down? Why not one that builds up? For instance—Postum made with hot milk. It contains no drug—no artificial stimulant.

A Hot Drink Children Love

Only the most wholesome ingredients are used in making Postum—just whole wheat and bran roasted to a turn and slightly sweetened. Postum-made-with-hot-milk combines all the nourishing qualities of milk with the wholesomeness of Postum. Even children who do not like milk alone, find Postum-made-with-milk delicious. What a contrast to coffee! What a difference to the child. Postum is a product of General Foods.

THESE FACTS are printed in the belief that they will interest you and in the hope that you will give your cooperation to this campaign to abolish the coffee drinking habit among school children.

WITHIN THE REACH OF MILLIONS

THE most valuable things on earth are the commonest things. Gifts of Mother Nature—air, rain, sunlight and colors in the sky, grass underfoot and foliage overhead. Gifts of human nature—love, loyalty, handclasps and friendly speech.

Then, of material things, some of the most useful are the commonest and cheapest. These we take almost for granted. There is no way to reckon their worth.

It is a great tribute to the value of the telephone that within a few short generations it has come to be ranked among these common things. Its daily use is a habit of millions of people. It speeds and eases and simplifies living. It extends the range of your own personality. It offers you gayety, solace, security—a swift messenger in time of need.

Daily it saves untold expense and waste, multiplies earning power, sweeps away confusion. Binds together the human fabric. Helps the individual man and woman to triumph over the complexities of a vast world.

You cannot reckon fully the worth of so useful and universal a thing as the telephone. You can only know that its value may be infinite.

Recommend it* in cases of *Constipation, Stomach and Skin Disorders*

FLEISCHMANN'S YEAST is of very decided value in treating disorders which the physician has to deal with every day.

The reason Fleischmann's Yeast is so desirable in cases of constipation is that it gently stimulates peristalsis without forming a dangerous habit.

In digestive disorders, it stimulates gastric secretions and supplies vitamins B and G, so important in relation to the appetite, as well as vitamin D.

In furunculosis, acne and other common suppurative skin disorders, Fleischmann's Yeast has a very well-known effect. It has now been discovered that it has the peculiar ability actually to increase the skin's

so-called "self-disinfecting" power.

*Fleischmann's fresh Yeast is the only yeast that is rich in *three* vitamins. Advise just three cakes daily—one before each meal, or between meals and at bedtime. It may be eaten either plain, broken up in small pieces, or dissolved in water (preferably about a third of a glassful).

Is It Advertised

in the

AMERICAN JOURNAL of PUBLIC HEALTH?

"Has the American Public Health Association ever accepted for advertising in the Journal such and such an article or product?" is a question frequently asked, the assumption being that products, equipment and services advertised in the American Journal of Public Health are safe to buy, prescribe, specify or recommend.

The assumption often is that aids to health protection and promotion not appearing in the Journal are not worthy of professional support.

Health authorities appreciate that manufacturers and distributors marketing the things used in modern health work have helped immeasurably in disease prevention and health building. Not all such things are advertised in the Journal, but health workers are right in using its advertising pages as their first guide. When the answer to the question "Is it advertised in the Journal?" is "Yes," then that advertiser should be patronized. It is only fair that readers should give preference in their buying to the advertisers who are supporting their magazine.

It is fair, too, to let Journal advertisers know that their announcements are read, and that they influence readers to buy.

It is not safe to neglect the advertising pages of the Journal. New products of public health significance are being developed constantly, many of them evolving as the commercial applications of scientific discoveries made by members of this Association.

The urgent recommendation is made that the advertising pages be scanned with care month by month, and that the advertisers be made aware of the interest of readers in correspondence and in patronage.

This practice can result in nothing but good for the public health worker, the advertiser and the Journal.

Scolded for C's *that really stand for coffee!*

IT is hard to believe—that in many sections of this country over half the children of grade and high-school age drink coffee daily. Yet extensive surveys show this to be true. And also—that children who drink coffee are less efficient in their studies than those who do not drink it.

Thousands of parents have become so used to coffee that they have failed to realize the harm it can do when given to their children.

When you encounter such cases, isn't Postum made with milk an excellent suggestion? Isn't it an ideal hot drink for children? It is not a drink that tears down, but a drink that builds up. Wholesome, nourishing—it contains no caffeine, no artificial stimulant.

Postum is simply whole wheat and bran,

roasted and slightly sweetened. And Postum made with milk is not only a nourishing drink, but a drink children love—even children who turn up their noses at plain milk.

Postum costs less than $\frac{1}{2}\text{¢}$ a cup. It comes in two forms—Instant Postum, made instantly in the cup, and Postum Cereal, the kind you boil. Postum is a product of General Foods.

If you will write us we will be glad to send you a special gift package containing a full-size package of Instant Postum, together with samples of Grape-Nuts, Grape-Nuts Flakes, Post Toasties, Post's Whole Bran, and Post's Bran Flakes. General Foods, Dept. P V-433, Battle Creek, Michigan. If you live in Canada, address General Foods, Ltd., Dept. P V-433, Cobourg, Ontario.

Preliminary tests show it* gives the best *transfer of Vitamin D* *to Mothers' Milk*

FLEISCHMANN'S YEAST has a very important new usefulness as a result of its richness in vitamin D.

It is now widely known by physicians that mothers' milk normally does not contain vitamin D in sufficient quantities. As a result, it is necessary to supplement the nursing child's diet with a direct administration of this vitamin.

To this, however, there are in the case of very young infants obvious disadvantages.

Tests now show that the vitamin D potency of mothers' milk itself can be increased. Preliminary results from a series of tests with lactating mothers indicate that this transfer of vitamin D from the diet to mothers' milk *is best accomplished with Fleischmann's Yeast.*

Every cake of Fleischmann's Yeast is now "irradiated" with ultra-

violet rays. Every cake has a known vitamin D potency . . . greater than that of any other food. And in addition it is, of course, extremely rich in vitamins B and G, also essential in the diet particularly during lactation and pregnancy.

*Only *Fleischmann's* fresh Yeast contains all three of these vitamins, together with the other well-known nutritional and therapeutic elements of fresh yeast.

Simply recommend three cakes daily — either plain, or dissolved in water, milk or fruit juice.

"... will help toward an understanding of the social medical problem! Admirable and rich in information!"—James P. Warbasse, M.D., in *The Survey*.

HOW TO BUDGET HEALTH

By EVANS CLARK

Director, Twentieth Century Fund

What can we do to assure adequate medical care for everyone at moderate cost? Must the burden of this cost on communities, philanthropy and hospitals continue to grow indefinitely? This book provides helpful answers to these questions. It offers a constructive plan of medical guilds for doctors and patients, to answer the demand of public health officials, hospitals and local communities for adequate medical care at a reasonable and predetermined cost.

The book is at once a practical working manual on the functioning of medical guilds and a reference work presenting a vast array of facts on the entire problem of medical care from the economic point of view. Detailed and authoritative, it will be of the greatest assistance to everyone interested in solving this most pressing problem of adequate medical care at moderate cost. To get the book for FREE EXAMINATION, use the coupon. Price \$4.00.

Enthusiastic Endorsement!

"A timely, interesting, practical sequel to the recent report of the Committee on the Costs of Medical Care. A contribution of much interest."
—*New York Times*

"Conservative and excellently conceived. Marks a much more important milestone in the great problem of medical economics than I thought could be obtained."—Dean M. C. Winternitz, *School of Medicine, Yale University*

"From the standpoint of the Committee on the Costs of Medical Care, I am delighted to have it come out at present. One of the most fundamental and important contributions ever made on the subject."—Dr. C.-E. A. Winslow, *School of Medicine, Yale University*

"An important contribution."—Dr. Haven Emerson

"I'll call you up!"

A HUSBAND bids his wife good-bye as he leaves in the morning. "I'll call you up," he says reassuringly. A guest leaves after a pleasant week-end. "I'll call you up," she tells her hostess. An executive sits at his desk handling varied business matters, large and small. "I'll call you up," he says.

"I'll call you up" is a phrase that has become part of our language and part of our modern security. It is a phrase of confidence and a phrase of friendship. Implied in it is a nearness to everything and everybody.

The familiar gesture of lifting the telephone receiver holds boundless possibilities. It may avert a danger, end an anxiety, insure an order. Or it may be for some trivial pleasant purpose—a jest to be shared, a greeting to be spoken.

Over the telephone speed the thoughts that change destiny, bring new hope to the wondering and greater achievement to the ambitious. Think what this world would be like if you could not telephone so easily to so many people. No one is far away when you can say—"I'll call you up."

For “run-down” condition recommend 3 cakes a day

WHEN patients feel “all run down”—with no definite, localized symptoms—the physician knows that digestive disorder is all too frequently the underlying cause.

In cases involving faulty elimination, with loss of appetite, constipation, digestive and skin disorders, the therapeutic value of fresh yeast has been proved time and again.

Fleischmann's Yeast, as you know, is not habit-forming. Its effect on the intestines is gentle rather than drastic. And it has certain very high nutritional values as well.

For example, Fleischmann's Yeast is now the richest of all foods in vitamin D. It is also very rich in vitamins B and G, so important

in restoring the appetite and aiding the digestive process.

Simply recommend 3 cakes daily—before meals, or between meals and at bedtime. It can be eaten just plain, in small pieces, or dissolved in a third of a glass of water. Since Fleischmann's fresh Yeast is the only kind that contains three vitamins, it should always be specified by name.

Graduated Glassware that is retempered like fine steel . . .

RETEMPERING is just as important to fine laboratory glassware as annealing is to fine steel. For this reason every piece of Kimble Exax Graduated Glassware is passed through a specially designed annealing oven or lehr, where it is thoroughly retempered, removing all strains and weak spots. The resultant product is sturdy, and assured of long life and dependable service.

All calibration lines and numerals on Kimble Exax Graduated Glassware are filled with a new blue glass enamel, fused-in as an integral part of the glassware. The chemical industries, the clinical and bacteriological fields, have received this new Blue Line glass-

ware with great enthusiasm. It is easier to read, errors are minimized, and results are uniform and accurate.

Kimble burettes, flasks, cylinders, pipettes and all other units of Exax Graduated Glassware are carefully tested and retested by experts to prevent errors and eliminate blemishes, or imperfections. The fact that the nation's finest research, industrial and clinical laboratories specify and use Kimble Graduated Glassware stamps it definitely as "AMERICA'S STANDARD OF ASSURED ACCURACY"

Stocked by leading Laboratory Supply Houses throughout the United States and Canada.

Every expectant and
nursing Mother needs
the three
vitamins
it contains

DURING and after pregnancy and the period of lactation is the time when the human system is most heavily taxed. Certain dietary precautions are now recognized as essential, both for the mother and the unborn or nursing child, at this time.

Vitamin D, for example, must be present in sufficient quantity in the diet to enable the mother properly to absorb and utilize the calcium and phosphorus in her food. And vitamins B and G are necessary for their effect on the mother's general health and the appetite and growth of the child.

Fleischmann's Yeast—now specially "irradiated"—is the richest food source of this group of three vitamins. Each cake con-

tains 60 Steenbock vitamin D units—the equivalent of a teaspoonful of standard cod liver oil.

The vitamin D in Fleischmann's Yeast not only helps the mother to replenish her own stores of calcium and phosphorus, thus protecting her bones and teeth. This vitamin is also transmitted directly to the nursing child—through the medium of the mother's milk.

Because of its exceptional vitamin richness, as well as for its gentle "regulative" effect, Fleischmann's Yeast is being more and more widely recommended during pregnancy and nursing. Prescribe three cakes of *Fleischmann's Yeast* a day—just plain, or dissolved in water, milk or fruit juice.

SCHOOL OF HYGIENE AND PUB- LIC HEALTH OF THE JOHNS HOPKINS UNIVERSITY

THE SIXTEENTH SESSION BEGINS OCTOBER 2, 1933

Opportunities for instruction and investigation will be offered in Public Health Administration, Epidemiology, Bacteriology, Immunology, Protozoology, Biostatistics, Sanitary Engineering, Helminthology, Medical Entomology, Physiology as applied to Hygiene, Biochemistry, Sanitary Law, Personal, Social and Mental Hygiene, etc. Practical work is provided through the assistance of the city and state departments of health and other organizations, and arrangements are made for field work during the summer. Courses are organized on a quarterly basis, each quarter consisting of approximately eight weeks. Students may enter the school as candidates for a degree or as special students at the beginning of any quarter. Men and women are admitted on the same terms.

Courses are arranged leading to a Certificate in Public Health, and to the degrees of Doctor of Public Health, Doctor of Science in Hygiene, and Master of Science in Hygiene. The details in regard to the requirements for matriculation in these courses will be forwarded upon application.

THE MULTIPLICATION OF YOU

A NEIGHBOR, passing by, glances through your window and sees you in the living-room. But you are around the corner on Main Street, ordering from the druggist. You are in a nearby town, chatting with a friend. You are in a distant city, delivering a message of cheer and reassurance. You are across a continent, or an ocean, talking clearly and easily, as if distance had ceased to be. . . . Your neighbor, returning, glances in again. You are still in your living-room.

Your telephone is you. In a moment it multiplies and projects your personality to many different places and many different people, near or far. Part of your very self is in every telephone message—your thoughts, your voice,

your smile, your words of welcome, the manner that is you. The extraordinary fact is that the more you use your telephone, the more it extends your power and personality.

All you see is the familiar telephone instrument in your office or home. Back of it are hundreds of thousands of trained employees, attending almost endless stretches of wire—so that you may call, easily and quickly, any one of more than sixteen million telephones in this country and an additional thirteen million in other lands.

You are cordially invited to visit the Bell System Exhibit in the Communication Building, Century of Progress Exposition, Chicago.

Here is an Important new fact *about the* **SKIN**

Normal skin, it has been found, has a definite self-disinfecting power. Investigations prove that this power, when sub-normal, can be materially raised by eating fresh yeast regularly.

IN the treatment of furunculosis and other suppurative skin disorders fresh yeast has long been known as an extremely effective aid. Important new light has now been thrown on its *mode of action* in such cases.

Research has shown that normal skin has a marked self-disinfecting power . . . and that a definite decrease in this power accompanies skin disorders. It has also been found that adding fresh yeast to the diet brings about a quick increase in the destruction of test micro-organisms applied to the skin's surface.

Of course, the gentle laxative action of

fresh yeast is decidedly helpful in treating skin disorders. By promoting regular elimination, it checks putrefaction and so helps prevent the absorption of toxins. Unlike drugs, fresh yeast actually *strengthens* the intestinal muscles instead of weakening them.

Moreover, the vitamin content of Fleischmann's Yeast raises the general resistance. It is the richest known food source of the group of vitamins B, G and D.

Prescribe this food in connection with other treatments in cases of furunculosis, acne, etc. Recommend three cakes a day—a cake before each meal—plain or dissolved in a third of a glass of water.

**A corrective
food...
very rich in
Vitamins B, G, D**

INDICTED FOR BURGLARY!

FOR YEARS he has robbed his body of the rest that is its due. Stealing an hour here . . . an hour there . . . trying to cover up his thefts with the false energy of stimulants.

Now he stands indicted . . . on the ragged edge of a breakdown.

You know the type. Usually he turns to you . . . asking you to fix things up. And if you find it advisable to bar coffee from his diet . . . you know how hard it will be for him.

Postum can be a real help

In such cases, Postum can make it easier for your patient. It is so good that forbidden drinks are soon forgotten. And it contains no caffeine . . . no stimulant of any kind. It is simply whole wheat and bran, slightly sweetened and roasted.

Postum comes in two forms, Postum Cereal, the kind that is boiled, and Instant Postum, made instantly in the cup. Don't miss the fascinating Postum show — Foods and Agricultural Building, Chicago World's Fair.

If you will write us we shall be glad to send a special gift package containing a full-size package of Instant Postum, together with samples of Grape-Nuts, Grape-Nuts Flakes, Post Toasties, Post's Whole Bran and Post's Bran Flakes. General Foods, Dept. PV-733, Battle Creek, Mich. If you live in Canada, address General Foods, Ltd., Dept. PV-733, Cobourg, Ont. (This offer expires July 1, 1934.)

| Milk | X Var. |
| Eggs (Yolk) | XX Var. |
| CEREALS | |
| Barley | 0 |
| Oatmeal | 0 |
| Bread (Regular) | 0 |
| Rice | 0 |

Milk, butter, eggs and fatty fish are the only four common foods that contain more than traces of Vitamin D . . . and the first three of these contain variable amounts of this vitamin.

**A corrective food
rich in
Vitamins B, G, D**

CLINICIANS AGREE that pregnant and nursing mothers today get too little vitamin D, even when they eat a "varied" diet. Only four common foods contain more than a trace of it, and three of these are undependable sources. And the body cannot store for long the small amounts absorbed from limited exposure to the summer sun.

As you know, vitamin D controls the calcium and phosphorus content of the blood. Even if the mother receives sufficient vitamin D to prevent rickets in the child, she may not get enough to replace the calcium and phosphorus drawn from her own system.

Adding Fleischmann's Yeast to the daily diet is an easy way to make sure that the expectant or nursing mother receives enough vitamin D. Now "irradiated," Fleischmann's Yeast is the richest food source of vitamin D. Each cake contains 60 Steenbock vitamin D units—the equivalent of a full teaspoonful of standard cod liver oil.

In addition, Fleischmann's Yeast is very rich in vitamins B and G and has a gentle laxative and tonic action, as you know.

Simply recommend 3 cakes a day—one before each meal—dissolved in water, milk or fruit juice.

Alum Precipitated DIPHTHERIA TOXOID

(Gilliland)

Single Injection

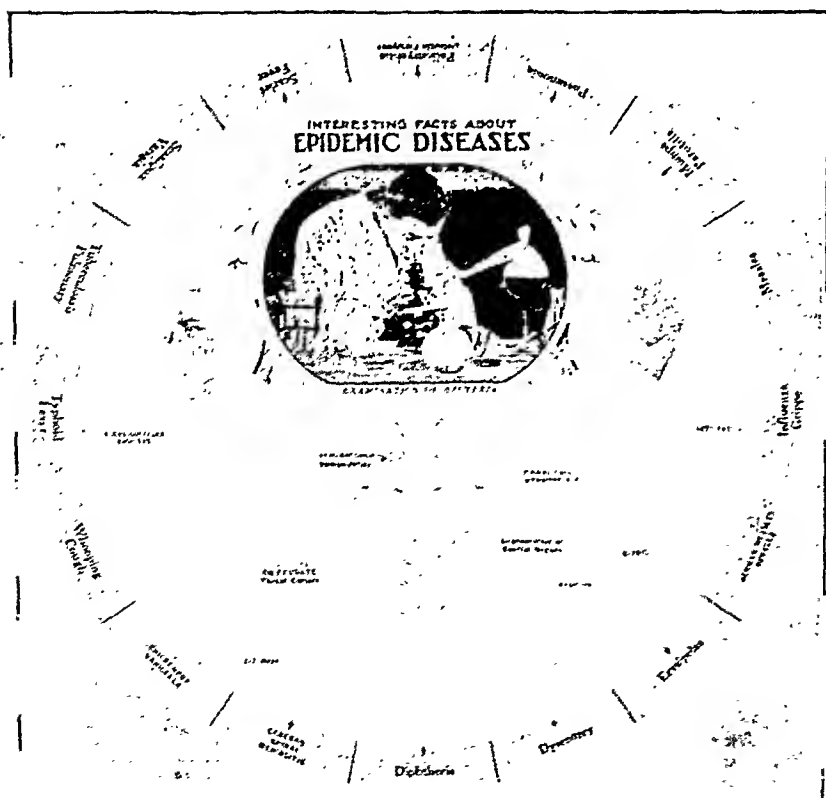

The superior immunizing value and the higher percentage of immunity following the use of a single injection of Alum Precipitated Toxoid has been demonstrated.

J. A. M. A., 100:14, Apr. 8, 1933; *J. Med. Assoc. State of Ala.*, 2:8, Feb., 1933.

Supplied in packages sufficient for One, Ten and Fifteen Treatments.

Additional Information and Prices on Request

The Gilliland Laboratories, Marietta, Pa.

Here on a circular revolving plaque 10 inches in diameter are given important facts about 32 communicable diseases.

The pointer is set to the disease about which information is desired and through skillfully cut openings appear the cause, prophylaxis, complications, temperature, diagnostic sign, pathology, case mortality, quarantine period and incubation period.

This chart is the work of Dr. Charles V. Craster, Health Officer of Newark, N. J., and is being sold through the Syndicated Health Bulletin Service of the A.P.H.A.

Price \$35 each, including postage

Special prices in quantities

FRIEND AND NEIGHBOR

CLOSE to those who live in small towns, and farther out upon the farms, is the helpful service of the telephone operator. In the truest sense, she is both friend and neighbor. Ties of kinship and association bind her to those whose voices come across the wires.

Bright and early in the morning she puts through a call that helps a farmer locate a drill for sowing oats. Another connection finds out if Jim Thomas, "over near Bogard," is feeding a bunch of calves and needs any shelled corn. Another gets the latest price on heavy hogs for Bill Simpson.

Through the day she aids in calling a doctor for Mrs. Moore, whose baby is ill. Plugs in an emergency call that sends an ambulance east

of town. Puts through a long distance call for Bob Roberts, whose boy attends the state college. Then, through the night, stands ever ready to help those in need.

Constantly in her mind and activities is one fixed, guiding purpose . . . "*Speed the call!*" And the further thought that she serves best when she serves with courtesy and understanding.

In the bustle of the city, as in town and country, that is the creed of every employee of the Bell System. Its faithful observance in so large a percentage of cases is an important factor in the value of your telephone service.

Accuracy in BLUE LINE EXAX PIPETTES

KIMBLE Blue Line Exax Pipettes are made from extra heavy tubing of very uniform bore, automatic-machine-made, carefully selected to eliminate pieces with blisters, stones or streaks.

IMPORTANT FEATURES:

1. Designed to deliver contents accurately and at a proper speed.
2. Delivery ends are tapered gradually; tips are ground and slightly bevelled.
3. The tops are smoothly finished.
4. Volumetric and other pipettes have joints that are carefully made without constrictions.
5. Expertly calibrated at 20°C to deliver capacity by free outflow through tip. No drainage period allowed. Where the small amount remaining in the tip is to be added this is indicated by a frayed band at the top.
6. All calibration lines are deeply acid-etched and filled with a durable blue fused-in glass enamel.
7. An entirely new type of calibration lining for accurate and rapid reading. Short lines for intermediate divisions with encircling lines at the main graduation points.
8. Retested and retempered (strain-free).

VOLUMETRIC AND CUSTWALD PIPETTES

If you *don't* prescribe Laxative FOODS... your patients will take weakening DRUGS

IN THIS DAY of constipating diets and sedentary lives, a large percentage of people suffer from intestinal stasis. Headaches and other discomforts naturally result. To secure relief, people all too often resort to various laxative drugs, which, when frequently used, are usually irritating and weakening.

Many doctors now save their patients from the effects of the repeated use of drugs. They simply recommend that Fleischmann's Yeast be added to the diet. This food has a gentle laxative action. It does not "gripe" or irritate. The effect of its continued use is to *strengthen*

en instead of weaken the intestinal muscles.

In addition to this cleansing property, Fleischmann's Yeast is very rich in three vitamins—VITAMINS B, G and D. It adds to the nutrition and well-being of the patient in many ways.

Fleischmann's fresh Yeast is available to all your patients. Recommend that they make use of it. Optimal benefits follow the regular eating of three cakes a day, a cake before each meal, or between meals and at bedtime, plain or dissolved in a third of a glass of water.

**A corrective
food...
very rich in
Vitamins B, G, D**

Is It Advertised

in the

AMERICAN JOURNAL of PUBLIC HEALTH?

“Has the American Public Health Association ever accepted for advertising in the Journal such and such an article or product?” is a question frequently asked, the assumption being that products, equipment and services advertised in the American Journal of Public Health are safe to buy, prescribe, specify or recommend.

The assumption often is that aids to health protection and promotion not appearing in the Journal are not worthy of professional support.

Health authorities appreciate that manufacturers and distributors marketing the things used in modern health work have helped immeasurably in disease prevention and health building. Not all such things are advertised in the Journal, but health workers are right in using its advertising pages as their first guide. When the answer to the question “Is it advertised in the Journal?” is “Yes,” then that advertiser should be patronized. It is only fair that readers should give preference in their buying to the advertisers who are supporting their magazine.

It is fair, too, to let Journal advertisers know that their announcements are read, and that they influence readers to buy.

It is not safe to neglect the advertising pages of the Journal. New products of public health significance are being developed constantly, many of them evolving as the commercial applications of scientific discoveries made by members of this Association.

The urgent recommendation is made that the advertising pages be scanned with care month by month, and that the advertisers be made aware of the interest of readers in correspondence and in patronage.

This practice can result in nothing but good for the public health worker, the advertiser and the Journal.

Every expectant and nursing mother needs this vitamin

—yet note its scarcity in all these foods

PERHAPS more than any other element, expectant and nursing mothers need vitamin D. Without it, the bone-building calcium and phosphorus in their food cannot be properly utilized.

Even a "varied" diet, however, fails to supply *enough* vitamin D. Only four common foods contain more than a trace of this vitamin, and even three of these in undependable amounts. And the body cannot store for long the small amounts absorbed from limited exposure to the summer sun.

Therefore, it is not enough to prescribe foods rich in phosphorus and calcium. Special measures are needed to provide vitamin D *as well*.

An easy way is to add Fleischmann's fresh Yeast to the diet. Now "irradiated," each cake contains 60 Steenbock vitamin D units—the equivalent of a full teaspoonful of standard cod liver oil.

Fleischmann's Yeast is also very rich in vitamins B and G—very important in pregnancy and lactation—and has a gentle laxative effect and general tonic action on the system as well.

Simply recommend three cakes a day.

... Announcing ...
 Alum Precipitated
 DIPHTHERIA TOXOID
 (Gilliland)

Single Injection

The superior immunizing value and the higher percentage of immunity following the use of a single injection of Alum Precipitated Toxoid has been demonstrated.

J. A. M. A., 100:14, Apr. 8, 1933; *J. Med. Assoc. State of Ala.*, 2:8, Feb., 1933.

Supplied in packages sufficient for One, Ten and Fifteen Treatments.

Additional Information and Prices on Request

The Gilliland Laboratories, Marietta, Pa.

Seven Years' Use has demonstrated the value
 of the SURGICAL SOLUTION of
Mercurochrome H.W. & D.
 in Preoperative Skin Disinfection

THIS preparation contains 2% Mercurochrome
 in aqueous-alcohol-acetone solution and has
 the advantages that:

Application is not painful.

It dries quickly.

*The color is due to Mercurochrome and
 shows how thoroughly this antiseptic agent
 has been applied.*

Stock solutions do not deteriorate.

Now available in 4, 8, and 16 oz. bottles and
 in special bulk package
 for hospitals.

Literature on request

This seal denotes acceptance of
 Mercurochrome for New and
 Nonofficial Remedies by the
 Council on Pharmacy and
 Chemistry of the American
 Medical Association.

Clinical on Dietary Control

GINGIVITIS

| | |
|--|--------------|
| 1st year (standard diet), incidence | 74.9% |
| 2nd year (standard diet + citrus fruit juices) . | 12.4% |
| 3rd year (standard diet, recheck period) . . | 60.3% |

DENTAL CARIES

| | |
|--|--------------|
| 1st year (standard diet), incidence | 78.0% |
| 2nd year (standard diet + citrus fruit juices) . | 33.7% |
| 3rd year (standard diet, recheck period) . . | 83.4% |

Three and a half year study of 440 Mooseheart children by The Sprague Memorial Institute at the University of Chicago shows citrus fruit juices to be an important nutritional factor in the control of gingivitis and of dental caries

DEFINITE progress in establishing the exact relationship between diet and dental disorders is reported in "Diet and Dental Health," a monograph soon to be published by University of Chicago Press.

Following one year each of clinical control and test periods and one and a half years of recheck, these conclusions were reached:

Standard Diet Inadequate

"1. The average American diet is adequate in calories but appears to be deficient in certain substances that are requisite to dental health. This dietary deficiency may be the ultimate cause of much of the gingivitis, pyorrhea and dental caries with which we are afflicted.

"2. Gingivitis and dental caries can occur in the majority of a large group of children who are receiving a quart of milk, one and one-half ounces of butter, a pound of vegetables, half a pound of fruit and nearly one egg a day. These foods do not, therefore, contain substances that are specifically antagonistic to gingivitis or dental caries.

Citrus Fruits Effective

"3. The addition of a pint of orange juice and the juice of one lemon to a diet that is nearly adequate in all other re-

spects supplies something that leads to a disappearance of most of the gingivitis and an arrest of about 50% of the dental caries.

Three Ounces Not Enough

"4. Dental caries again becomes rampant and gingivitis redevelops in most of the cases when the citrus fruit intake is reduced to three ounces a day for one year. Three ounces is not enough.

"5. Children display a definite tendency toward the development of carious lesions which is nil or low in some cases and high in others. This tendency can, perhaps, be ascribed to heredity. The administration of an adequate amount of citrus fruit juice to a diet that is nearly adequate in other respects reduces the intensity of the carious process; but does not completely remove the effects of the inherent tendency in all cases.

Growth Accelerated

"6. Orange and lemon juice contain something that acts as a growth stimulus to children."

How Study Was Begun

The study culminating in these conclusions was undertaken after preliminary work by Dr. Milton T. Hanke, Associate Professor of Biochemistry in the Department of Pathology, and a member of The Sprague Memorial Institute at the University of Chicago, in collaboration with the members

CALIFORNIA FRUIT GROWERS EXCHANGE...Marketers of...

BLUE LINE EXAX CYLINDERS

for Assurance

THE graduated cylinder is one of the mainstays in scientific laboratory work. Its calibration must be accurate if results are to be relied upon. Kimble Blue Line Exax Cylinders—blown in paste moulds to produce a highly polished surface—permit reading of all liquid levels without error or distortion.

IMPORTANT FEATURES

1. Each cylinder is calibrated at 20°C at enough points to assure accuracy of intermediate divisions.
2. Lining and numbering are done by automatic machines.
3. All lines are deeply acid-etched and filled with a durable blue glass enamel, actually fused in.
4. An entirely new type of calibration lining for accurate and rapid reading. Short lines for intermediate divisions with encircling lines at the main graduation points.
5. All Kimble Blue Line Exax Cylinders are retested, and are retempered (strain-free) to eliminate weak spots.
6. The lips are finished so that liquid can be poured slowly without running down the sides.
7. All bottoms are ground so as to rest perfectly level.

The following tolerances are allowed:

| | | | |
|---------|-----------|----------|----------|
| 5 ml. | ±0.10 ml. | 250 ml. | ±1.4 ml. |
| 10 ml. | 0.10 ml. | 500 ml. | 2.6 ml. |
| 25 ml. | 0.30 ml. | 1000 ml. | 5.0 ml. |
| 50 ml. | 0.40 ml. | 2000 ml. | 10.0 ml. |
| 100 ml. | 0.60 ml. | | |

Stocked by leading Laboratory Supply Houses throughout the United States and Canada.

*Exhaustive monograph lists complete diets used in the most comprehensive clinical nutritional study of children on record—permitting correlations for various purposes.
This Advance Edition now offered at special pre-publication price of one dollar*

of the Chicago Dental Research Club. Upon the suggestion of this group and The Sprague Memorial Institute, the California Fruit Growers Exchange agreed to furnish fruit and additional funds to guarantee the completion of the research.

The California Fruit Growers Exchange also made available to the University of Chicago Press the forty-eight costly color engravings and other plates, which illustrate this monograph. This makes it possible for the Special Advance (\$1.) Edition to contain the identical full color illustrations that will be used in the regular \$4. edition.

Nutritionists: Send For Book

Nutritionists and Physicians, as well as Dentists, will find much of the clinical material in "Diet and Dental Health" directed to them. Tables give precise data, such as serum calcium, oral bacteriology, etc., on all children included in the three and a half year Mooseheart study group. This permits correlations for various purposes. The Mooseheart research is easily the most comprehensive clinical nutritional study of children on record. Only a limited number of subscriptions for the monograph can be made available to the professions at \$1., and an early return of the coupon and remittance is urged.

"WHERE TO, PLEASE?"

SCARCELY a day passes—sometimes scarcely an hour in the day—that you do not go visiting by telephone. It is truly the magic carpet that transports you, quickly and easily, to places you would like to be and people you would like to see.

Who can estimate the value of the telephone in the daily lives of millions of men and women . . . in time and money saved, in increased efficiency, in security and priceless help in time of need!

Contact, communication, swift interchange of ideas—these

benefits the modern world offers you. The telephone is one of the chief instruments by which you can seize them. With it at your elbow you are ready for what may come—for opportunity, for emergency, for the brief word that may open a fresh chapter in your life.

Within the next twenty-four hours, sixty million telephone calls will be made over Bell System wires—each a separate, individual transaction, complete in itself. Yet your own calls will go through as quickly and efficiently as if the entire system had been built especially for you.

SINCE THEY WON'T TAKE EXERCISE THEY MUST TAKE LAXATIVES...

Prescribe this laxative FOOD instead of weakening DRUGS

PEOPLE refuse to adapt their dietary to their sedentary ways of living. And they cannot or *will* not exercise enough to enable their systems to eliminate the constipating foods they indulge in. So naturally a large number suffer from constipation and attendant ills.

Left to their own devices, people usually resort to laxative drugs which often are drastic and irritating in their action and frequently have a weakening effect over a period of time.

This objection is not true of Fleischmann's Yeast. It is a *food*, with very valuable corrective properties. It does not "gripe" or irritate. It is not habit

forming. It has a gentle cleansing effect. It softens impacted masses and when used regularly *strengthens* the intestinal muscles.

Fleischmann's Yeast is at least a partial substitute for exercise and sunshine. It provides the laxative effect which exercise gives. It supplies the "sunshine" vitamin D. In addition, it is extremely rich in vitamins B and G.

Advise your patients to make use of this food. Simply recommend three cakes a day—before meals, or between meals and at bedtime—plain, or dissolved in a third of a glass of water.

A corrective
food...
very rich in
Vitamins B, G, D

CALIFORNIA FRUIT GROWERS EXCHANGE...Marketers of...

"THE addition of a pint of orange juice and the juice of one lemon to a diet that is nearly adequate in all other respects supplies something that leads to a disappearance of most of the gingivitis and an arrest of about 50% of the dental caries."

This is one of the conclusions announced in "Diet and Dental Health," a monograph published by the University of Chicago Press. It reports the results of a three and one-half year study made at Mooseheart by The Sprague Memorial Institute at the University of Chicago.

American Diet Deficient

"The average American diet," the conclusions also state, "is adequate in calories but appears to be deficient in certain substances that are requisite to dental health. This dietary deficiency may be the ultimate cause of much of the gingivitis, pyorrhea and dental caries with which we are afflicted."

"Gingivitis and dental caries can occur in the majority of a large group of children who are receiving a quart of milk, one and one-half ounces of butter, a pound of vegetables, half a pound of fruit and nearly one egg a day. These foods do not, therefore, contain substances that are specifically antagonistic to gingivitis or dental caries."

Ample Citrus Fruit Juice Required

"Dental caries again becomes rampant and gingivitis redevelops in most of the cases when the citrus fruit intake is reduced to three ounces a day for one year. Three ounces is not enough."

"Children display a definite tendency toward the development of carious lesions which is nil or low in some cases and high in others. This

Entirely lacking in most foods...

the vitamin most needed in Pregnancy

You know the importance of vitamin D during pregnancy and lactation... without it the mother cannot properly absorb and utilize the calcium and phosphorus in her food—cannot adequately replace the phosphorus and calcium drawn from her own bone and tooth structure.

But do you realize the *scarcity* of this vitamin? There is no vitamin D in fruits and vegetables. Only *four* common foods contain more than a trace... milk, butter, eggs and fatty fish, and in the first three of these it is decidedly variable. And the body cannot long store the small amounts it may absorb from limited exposure to the summer sun.

Hence it is not enough to prescribe foods rich in phosphorus and calcium. Special provision should *also* be made for a regular supply of vitamin D.

Many doctors make such provision by prescribing three cakes of Fleischmann's Yeast daily. Now specially "irradiated," each cake has a potency of 60 Steenbock vitamin D units—the equivalent of a full teaspoonful of standard cod liver oil.

In addition, Fleischmann's Yeast is very rich in vitamins B and G, so necessary for their influence on the mother's digestion and the growth of the nursing child. And Fleischmann's Yeast is, of course, gently laxative.

Recommend 3 cakes a day, before each meal—dissolved in water, milk or fruit juice.

| FOOD | VITAMIN D |
|-----------------------|-----------|
| VEGETABLES | |
| Asparagus | 0 |
| Beans, Lima | 0 |
| Beans, String | 0 |
| Beets | 0 |
| Cabbage | 0 |
| Carrots | 0 |
| Celery | 0 |
| Lettuce | 0 |
| Potatoes | 0 |
| Spinach | 0 |
| FRUITS | |
| Apples | 0 |
| Bananas | 0 |
| Grapefruit | 0 |
| Lemon juice | 0 |
| Orange juice | 0 |
| Pineapple | 0 |
| Prunes | 0 |
| MEATS AND FISH | |
| Meat | 0 |
| Liver | 0 |
| Fish (Average) | Trace |
| Fish (Fatty) | XXX |
| Oysters | Trace |
| DAIRY PRODUCTS | |

| Buttermilk | 0 |
| Cheese | 0 |
| Milk | X Var. |
| Eggs (Yolk) | XX Var. |
| CEREALS | |
| Barley | 0 |
| Oatmeal | 0 |
| Bread (Regular) | 0 |
| Rice | 0 |

Chart explains why most expectant and nursing mothers do not get enough vitamin D. Only four common foods contain more than a trace. Its *richest* food source is now Fleischmann's fresh Yeast.

Dental Caries

3½-Year Clinical Study

Nutritionists: Monograph gives full details of the most comprehensive nutritional study of children ever made

tendency can, perhaps, be ascribed to heredity. The administration of an adequate amount of citrus fruit juice to a diet that is nearly adequate in other respects reduces the intensity of the carious process; but does not completely remove the effects of the inherent tendency in all cases.

Rate of Growth Improved

"Orange and lemon juice contain something that acts as a growth stimulus to children."

How Study Was Begun

This study was the outgrowth of preliminary work by Dr. Milton T. Hanke, Associate Professor of Biochemistry in the Department of Pathology, and a member of The Sprague Memorial Institute at the University of Chicago, in collaboration with the Chicago Dental Research Club.

At the instance of this group and the Institute, the California Fruit Growers Exchange agreed to furnish fruit and additional funds to guarantee the completion of the research.

And for the monograph, the California Fruit Growers Exchange made available to the University of Chicago Press forty-eight costly color engravings and other plates. This makes it possible for the Special Advance (\$1) Edition to contain the identical full-color illustrations to be used in the regular \$4 edition.

Nutritionists: Send For Book

Nutritionists and Physicians, as well as Dentists, will find much of the clinical material in "Diet and Dental Health" directed to them. Tables give precise data, such as serum calcium, oral bacteriology, etc., on all children included in the

three and a half year Mooscheart study group. This permits correlations for various purposes. The Mooscheart research is easily the most comprehensive clinical nutritional study of children on record. Only a limited number of subscriptions for the monograph can be made available to the professions at \$1, and an early return of the coupon and remittance is urged.

THE CRISIS IN PUBLIC HEALTH

By

S. WEIR NEWMAYER, M.D.

"It is on this point that the greatest danger exists at the present moment. In many localities the non-presidential year is the time for city elections, and all over the United States at this moment the programs of health and of education are being used as means to attract votes to one side or another. What will happen after the new riders have mounted the horse? Will the vital public health set-up which has protected our millions be permitted to continue or will we have the makeshifts attempted in some localities adopted in many localities? Let us hope that all health activities may remain in full force—that even the most selfish office-holder realizes that there can be no relaxation or compromise in maintaining health. . . . Surely Reconstruction Funds should be spent on medical power and on nurse power to reclaim and improve human beings. 'Life, liberty and the pursuit of happiness' are not only measured in economic projects. Perhaps there are other resources and other workable plans which will forestall that greater crisis, the crippling of public health!"

* * * * *

The article from which these are excerpts is a challenge. It should be thoughtfully read by every public health worker and executive.

In the November issue of *The Trained Nurse and Hospital Review* also appear other pertinent public health articles and below:

B-K HALTS THE SPREAD OF ATHLETE'S FOOT

LABORATORY tests prove that B-K kills instantly on contact the Trichophyton organisms which cause Athlete's Foot . . . that dreaded infection from which it is estimated 90 per cent of college athletes and 50 per cent of our general adult population suffer.

To help prevent the spread of Athlete's Foot, the Committee on Bathing Places of the American Public Health Association recommends the daily use of a hypochlorite solution (such as B-K) to disinfect locker room floors, benches, swimming pool equipment and shower bath floors . . . also for disinfecting the feet after leaving the shower room!

B-K Now Available in Liquid or Powder Form

B-K POWDER is more economical and can be added direct to the water for sterilizing and disinfecting, or made into a stock solution and used as per directions for B-K Liquid. Many still prefer B-K Liquid, however, because it provides a dependable ready-made solution at a low price.

A HALF CENTURY OF PUBLIC HEALTH 1872—1922

In commemoration of the 50th Annual Meeting of the American Public Health Association in New York, in 1921, a series of historical articles were written and published in book form under the title "A Half Century of Public Health."

The period covered by the essays is notable for all time by remarkable discoveries in every branch of science, and particularly in medicine, both curative and preventive. The conception and development of the entire public health movement were carefully traced and summarized by the historians, and the result was, and is, a volume of far-reaching importance and significance.

As an outline of public health, "A Half Century of Public Health" has not been surpassed. It is brief, concise and accurate. It presents the history of every important branch of public health in nineteen chapters, each written by a specialist. The regular edition of "A Half Century of Public Health" has been exhausted long since. There remain less than 200 copies of the deluxe edition and on these the price is now lowered from \$10.00 to \$7.50.

This is the time to add "A Half Century of Public Health" to your library or to the library of a friend.

Number 1

Effectiveness of Child Health Programs in Ontario by Survey Methods*

JOHN T. PHAIR, M.B., D.P.H., F.A.P.H.A.

*Director, Division of Maternal and Child Hygiene, Provincial
Department of Health of Ontario, Toronto, Canada*

THE statistical incongruities associated with the annual reports of certain municipalities organized for work in the field of child hygiene, led the writer, some years ago, to attempt to arouse interest in accurate recording of local effort. This was beset with difficulties. Early in 1930, the department offered to assay the services in certain representative communities. The study upon which the data used in this paper are based was commenced in March, 1930, and completed only a few weeks ago. Our findings are presented with the belief that conditions in Ontario do not differ materially from those in other comparable provinces in Canada, or states in the United States.

While 13 cities were included in the survey, the infant and pre-school effort was not studied in 2—Toronto and Peterborough. The school health service was reviewed in 12. The local objectives were noted, and the records of work performed and results obtained in certain, selected years, were intimately examined.

The difficulties confronting the staff were even greater than I had imagined they might be. In most of the cities, records of work performed were kept on inappropriate forms, or on no forms at all. Calls made, consultations, or other efforts were unrecorded or inadequately recorded. In others, suitable record forms were available, but either their purpose was unappreciated by the staff, or their accuracy was not reviewed often enough to insure care in their keeping.

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 27, 1932.

In reviewing objectives with those responsible for local public health leadership, we found lack of knowledge, confusion and complacency muddled with earnestness and enthusiasm. An appreciation of the implications involved in a child hygiene program was lacking in many instances. Precept and practice were poles apart. Details of programs had so beclouded the main issue that the original conception was almost entirely lost sight of.

But let us be more specific! We found, in most of the centers, some interest in the possible relationship between indifferent obstetrics, an absence of prenatal and natal supervision, and the deaths occurring in the first month of life. This interest was purely academic in some; in others, it was manifested by the inclusion in the local program of time for prenatal visiting by the nursing staff, and in 2 centers municipally operated prenatal clinics were held. In none of centers concerned had the local authorities established intimate working relations with the medical profession of the community for the purpose of studying the best method of approaching this problem.

Increased hospitalization of maternity cases was apparently being encouraged in all communities, but whether this was part of an organized effort to influence maternal and infant deaths was not apparent. Forty-nine per cent of the births were in hospital. The death rate was apparently the same among these as among those born at home. It is interesting to note that of those women confined at home, 37 per cent were attended before, during, and after labor, by the Victorian Order of Nurses—an estimable organization, Dominion-wide in its scope, with branches in most of the large centers in Ontario—which offers bedside care to those unable to pay the ordinary fees demanded for such service. The standards of the service are high. The infant death rate, particularly in the first month, among those receiving this service was uniformly lower than for the city as a whole in every center in which they operated. Is this statistical fact the direct result of the contact between the nursing organization and the pregnant women? or the contact between the nursing organization and the attending physician? or both?

Despite the fact that prenatal supervision was a local objective, we could find records of only one-quarter of the pregnant women having been seen either by a physician or nurse before the onset of labor—not that I believe that only 25 per cent had prenatal care, but service rendered to the others was unrecorded. We were able to gauge the value of the prenatal service quantitatively only. Of those in which records were available, 29 per cent were seen during the first 6

months of pregnancy; 57 per cent were seen 3 or more times prior to delivery.

Appreciating, however, that an actual interest in the infant before it was born is a comparatively recent responsibility of health departments, we were inclined to be charitable in our criticism, and turned our attention to matters in which official interest was more actively demonstrable. We found that there was greater interest and less confusion in the minds of the municipal health staff when we discussed the subject in terms of infant deaths. The lessening of the infant mortality rate of this age group seemed to be the chief objective of most, and certainly was the yardstick by which all measured the success of their efforts. If it went down, whether justified or not, they took the credit; if it went up, the rise was either unexplained or was due to some cyclic epidemiological phenomenon not amenable to control.

In support of the efficiency of the local service, they told us how many children under 1 year attended the well baby clinics, and how often they came. This seemed to be the standard by which they desired their efforts to be measured. Nobody could tell us how many of the 8,428 infants born alive in the first 11 months of the year under survey, and who lived a month, were regularly under the care of the family physician or pediatrician. We ultimately uncovered the fact that about 17 per cent had been seen by a physician some time during their first year; whether it was to cure existing ills or prevent future ones, nobody knew. This was a definite weakness apparent in all the programs studied.

The local infant hygiene program was uniformly set in motion by what was known as a birth registration call by a member of the municipal nursing staff. The purpose of these introductory visits was vague in the minds of many of those making them. In many instances, they appeared to accomplish nothing more than a distribution of literature appropriate to the health needs of infancy, and a list of the municipally operated clinics. That the visits were made with faithfulness, however, is indicated by the fact that 76 per cent of these new arrivals were called upon. Our survey group was struck at this point with lost opportunity resulting from lack of appreciation by the nurse visitor as to the possibilities of this stage of the program.

In 5 of the cities only were medical men directly associated with the clinics carried on by the health departments. These were operated along orthodox lines, usually by physicians with a special interest in the field of child health. They received a small honorarium for their services in practically all centers. In the 6 cities in which there was

no medical attendant at the clinic, the gathering was described as a child health conference. The community nursing staff met the interested mothers at a given place, at a given time, and gave such advice as might possibly emanate from a nursing service. Irrespective of whether the gathering was a clinic or conference, the social or financial status of those attending had no bearing on their eligibility to be present—the socially prominent or socially obscure were equally welcome.

While clinic attendance was urged in every center, no uniform method of assuring its continuity was in effect; 49 per cent of those called on attended on at least 1 occasion, but only 53 per cent of those who came could be described as regular attendants. Adequate reasons for failure to return were hard to find. In some centers, there was the feeling that once they were made acquainted with the available facilities, the onus for failure to return was on the parents. In some, a home visit was paid following the first lapse in attendance; in others, one gathered that a modified clinic service was extended to those failing to attend regularly, through home visiting by the nursing staff. In 1 city only, had there been an attempt to analyze the reasons for failure to return. In the majority of centers the staffs seemed content to concentrate their efforts on those who were desirous of taking advantage of the service as offered and leave the balance to their own devices. Twenty-three per cent of all the children who lived over 1 month were regular clinic attendants.

Just what the clinic or conference offered those who came might very well be the subject of careful study—64 per cent of them were noted as having seen the clinic physician when the clinics were medically served. This did not mean that they had all been actually medically examined, however.

Group instruction was not attempted in any of the conferences. A child was weighed—if a degree of normal progress was maintained, apparently the mother was complimented; if failure to gain was noted, a casual inquiry was conducted. Few of the findings following this inquiry were ever recorded on the clinic form, however. Evidently the value of regular weighing as a gauge of physical progress was impressed upon the parents, and many on the advice of their private physician took their children to the center merely to have them weighed. Many of these gatherings had a social aspect: tea was served and the natural maternal pride in one's offspring was given an opportunity to manifest itself. The fact remains that many came and good must have resulted, but the extent of this good could not be measured. As was to be expected, the death rate among

the group of regular clinic attendants was lower than that for the municipality as a whole.

A review of the infant deaths was interesting, in that we found that of those stillborn, 49 per cent were delivered in hospital, and 39 per cent of these had had prenatal care; 49 per cent of those dying in the first month were born in hospital, and 47 per cent of these had had medical supervision during the period of pregnancy. Prematurity was described as the cause of death in 63 per cent of those dying during the first 24 hours, with congenital malformation the only other considerable cause of death. In those dying in the first week, prematurity was again responsible for the largest number of deaths, with cerebral hemorrhage second. Among those living over 1 week and dying within 1 month, prematurity is again noted as being responsible for a larger number of deaths than any other single cause. Gastro-intestinal diseases constituted the chief cause of death in the group living 1 month but dying within the first year.

Breast feeding was practised in 58 per cent of all and in 36 per cent of those dying within the first year. Breast feeding was supplemented by artificial feeding in 21 per cent of all and in 39 per cent of those dying during the first year. Artificial feeding was practised only in 21 per cent of all and in 25 per cent of those dying during infancy. Pasteurization was the vogue in every municipality.

The economic status of the parents of the children dying in the first year was as follows: good, 28 per cent; fair, 31 per cent; and poor, 41 per cent. The intellectual status was estimated as follows: 29 per cent were fully alive to their responsibilities as regards the health of their children; 35 per cent seemingly were not as child-health-conscious as the first group, but were aware of the existence of the service offered by the local health departments. In 36 per cent, the mental attitude toward health was poor.

PRESCHOOL AGE

The local health program as it affected children between 1 and 5 years was, in all but 2 centers, an attempted extension of the clinic and conference service offered to infants; the success of which may be gauged by the fact that 51 per cent of those attending the clinics as infants continued for a period of at least 1 year as toddlers. The number of these still attending at 5 years of age was negligible, however. The number registered at the clinic after they were 1 year of age was larger in some centers than had been imagined. Thirty-five per cent of all attending were examined by the clinic physician in the cities in which physicians were attached to the service.

In but few of the centers was there a concerted effort being made to arouse the interest of parents in having the family physician regularly examine these children. Opportunities for immunization against diphtheria, smallpox, and, in one or two places, whooping cough, were extended by the clinic. In the 2 cities referred to above, the clinic service was supplemented by an organized attempt to have the children of 4 years of age annually examined by either the family physician, on forms supplied for this purpose, or by the medical staff of the local health department, aided by physicians temporarily employed.

SCHOOL AGE GROUP

Details as to the type and size of the various municipalities included in the survey have been deliberately left out of this report, but it is necessary to state that in Toronto, only a section of the city was studied—a representative district being chosen by the local Health Department. The study in Hamilton was not completed in time to include it in this presentation.

In 7 of the municipalities, the school health service is carried on under the auspices of the local school authorities; in 5, it is an activity of the health department. In 4 of the former there is no medical man directly associated with the work. It has been thought wise, therefore, to separate the findings in these communities from those of the 8 centers in which physicians are included in the program. They are labelled, Group 1, and Group 2.

It was found in Group 1 (comprising those cities in which the work had medical leadership) that 51 per cent of the children in attendance at school were examined by the school physician during the 2 years under review; 37 per cent of these were examined with 1 parent present. (In 2 of the cities, parents are not invited to attend at the time of the examination.) The attendance of parents in cities in which this practice was in effect reached 47 per cent. Of the children examined, 7,217, or 41.5 per cent had notifiable defects; 9,914 defects were recorded; 3,600 were labelled as in need of supervision. Twenty-nine per cent of those with defects had one or more of these corrected during the 2-year period; 34.5 per cent of which were corrected upon notification only; that is, the statement given the parent at the time of the examination by the examining physician, or the notification sent home with those unaccompanied by parents, was sufficient to influence the parent in securing treatment. Seventy-eight per cent of the children with defects were noted as having abnormal tonsils or adenoid overgrowth which warranted treatment, and 12 per cent had a loss of visual acuity sufficient to necessitate the

advice of an oculist. Fifty-two per cent of the total defects found were abnormal tonsils. Dental defects were not included in the study.

In the 2 cities in which the parents were not encouraged to attend at the time of examination, the percentage of corrections was slightly lower than the others in this group—namely 27 per cent, but 60 per cent of these were effected without any other effort on the part of the staff than the original notification.

Twenty per cent of the corrected defects were corrected within 3 months of their discovery, while in 45.5 per cent a year or more elapsed before correction was finally complete, the reason for delay being inability to pay immediately for treatment in more than 50 per cent of cases. In 51 per cent of those corrected within 3 months, the child had been accompanied by a parent at the time of examination.

Of the large number uncorrected at the end of the 2-year period, less than 30 per cent gave financial reasons as their excuse for not having treatment established, indifference, procrastination, parental objection, being the reasons advanced in more than 60 per cent of the cases in which a reason was noted. Defects of vision were most readily corrected—50 per cent of those found being corrected within the period under study while only 26.5 per cent of the nose and throat conditions were terminated by treatment in the same period.

The family physician or specialist of the family's choice was responsible for the treatment in 69 per cent, while only 31 per cent were treated by charitable agencies. The presence of hospital outpatient services did not materially raise the percentage of those treated in centers so equipped.

Efforts to stimulate correction among the tardy were almost solely confined to home visits by the nursing staff. There was no uniform practice as regards such visiting in effect in the municipalities concerned. In some, the minimum number of visits were paid; in others, few, if any, of those suffering from defects were left unvisited; 34.5 per cent were corrected without call; 23 per cent were called upon once; 36 per cent were visited 2 or more times; no accurate information could be obtained about the balance. Home visits to those uncorrected were as follows—33 per cent had 1 visit, 42 per cent had 2 or more visits, and 25 per cent were unvisited. Corrections were found to be as prevalent in the centers where home visiting was not the vogue as in those where it was intensively carried out. It was apparently a factor, however, in expediting treatment by charitable agencies in such cases as required this type of treatment.

School attendance was noted to be more irregular among those children suffering from defects to the extent of 4.2 days per year. In no center was repetition of a grade considered to be an indication of the need for medical inquiry. The data relevant to improvement in attendance and scholastic progress following the correction of defects was not convincing enough to justify its inclusion.

In the 4 municipalities where the service was entirely in the hands of nurses, a smaller percentage of the children attending school was examined during the 2 years in question, namely 37 per cent. The number of children with notifiable defects was higher than in Group 1, as was the percentage of corrections—55 per cent and 36 per cent respectively. Thirty-four per cent of the defects corrected were done with notification only. While 22 per cent of the children found with defects had below normal vision, only 65 per cent of the defects were associated with the nose or throat. Sixty per cent of the vision defects were corrected and 25 per cent of those with abnormal tonsils.

A higher percentage of the defects found were corrected within 3 months after notification, namely 29. The percentage taking over a year was exactly the same as in Group 1—45.5. The commonest reason for delay in correction was again inability to finance treatment, and among those uncorrected, the number of those giving financial reasons as their excuse for non-correction was much greater than in Group 1—indifference, procrastination, and parental opposition to treatment being less than half what it was in the centers medically served. The family physician was responsible for treatment in a larger percentage of cases in these centers than in those in Group 1.

In Group 2, home visits were paid to 36 per cent of those ultimately corrected; 27 per cent received 2 or more visits, and 34 per cent were corrected merely as the result of notification. Among those uncorrected, 22 per cent had 2 or more home visits paid to them, 33 per cent had 1 visit, 31 per cent had none, and the balance were unrecorded.

The school health staff measurably contributed to the control of communicable disease by urging immunization and interesting the teacher in the prompt exclusion of children showing evidence of such conditions as impetigo, scabies and pediculosis. The number of children suffering from the major communicable diseases actually found by them, either in the school or in the home, except where such disease had already reached epidemic proportions in the community, was negligible.

Health teaching, as such, was not well done by the school health staff. They undoubtedly have, in some instances, stimulated the interest of the teacher in a more adequate presentation of the subject.

CONCLUSIONS

1. Few of those actually engaged in the field of child hygiene are alive to the need for accurate and adequate recording.
2. In many instances, the purposes of the service have become vague, or have never been appreciated.
3. The relationship between the medical profession and the official health services is not as intimate as might be desired, having in mind our ultimate objective.

Further, there are certain observations which are statistically supported, but which before their final acceptance, warrant careful review by those actually charged with the responsibility for the conduct of a municipal child health service. It is with the hope that the results of this study may prompt such departments to become periodically introspective, that they are presented:

1. The problem of providing all pregnant women with the maximum of prenatal and postnatal care is still a long way from solution.
2. Prematurity is apparently the outstanding factor contributing to the high infant death rate in the first month.
3. The local staffs are bending too much of their effort toward increasing the attendance at the official operating clinic, instead of urging that all children receive regular supervision by the medical men of the community.
4. There is no satisfactory health program in operation which is appropriate to the needs of the preschool age group.
5. We were not able to demonstrate that the school health staff materially aided in the control of communicable disease.
6. The percentage of so-called major defects is predominatingly abnormalities of the tonsils.
7. The percentage of defects corrected is lower than it should be and the present time consuming method of stimulating corrections is limited in its effectiveness.
8. The presence of the parent at the time of examination can increase the interest of both parents and child in health supervision and the establishment of desirable health practices; it aids in arriving at a more accurate conclusion as to the need for treatment; but does not stimulate prompt correction to the extent previously imagined.
9. The percentage of parents who are sufficiently interested in the well-being of their children to require only an intimation that they are physically below par, is fairly constant in all municipalities.
10. Corrections in centers best supplied with free treatment facilities did not exceed those in centers not so equipped, to the extent formerly presumed.
11. Without belittling the value of medical leadership—it was not impossible to operate what appeared to be a comparatively satisfactory school health service by nurses working alone.
12. Here and there, was evidence of sufficient appreciation of objectives, clarity of thought, and originality of execution to encourage us in the belief that an acceptable, sound, and convincing program could be evolved and maintained.

The Addition of Vitamin D Concentrate to Milk*

THEODORE F. ZUCKER, PH.D.

Assistant Professor of Pathology, Columbia University, New York, N. Y.

THE thought that milk should be the logical medium in which to offer "vitamin D" to infants and children is by no means new. Almost immediately after it had been clearly demonstrated that certain ultra-violet wave-lengths can confer antirachitic properties on food substances, attempts were made in Germany to put this idea into practice. The chief early obstacles in the way of successful activation of milk were the effect on taste and other properties, and the fear of toxic effects. Of late the irradiation of milk has met with a certain amount of success in some German cities. Cost has always been a consideration. The difficulties have apparently been successfully met in the work reported by Dr. George C. Supplee.

During the past years we have been engaged in the further purification and improvement of the antirachitic concentrate from cod liver oil on which we first reported in 1921; and we have recently perfected preparations of higher potency and purity which, when incorporated in milk, will not affect its taste.

For the purposes of study on a practical scale, one dairy has now been licensed to prepare such milk. The concentrate is furnished to the dairy as a "150 D" preparation, i.e., a preparation which by line test is 150 times as strong as the standard cod liver oil according to the Steenbock line test method. This concentrate, when diluted 1 to 12,000 in milk, will give a milk which contains approximately 150 units of "vitamin D" per quart, or the equivalent of 3 teaspoonfuls of cod liver oil. The preparations furnished to the dairy are carefully standardized and assayed. The incorporation can be done either by homogenization, by partial homogenization, or by another method without homogenization. By none of these methods is there any separation of the concentrate from the cream. In the non-homogenized milk the fat globules are of the same range of size as in

* Read as a part of the Symposium on Milks of Special Antirachitic Value before the Food and Nutrition Section of the American Public Health Association at the Sixty-first Annual Meeting at Washington, D. C., October 26, 1932. Other papers from the Symposium will be published later. The Report of the Committee on Milk and Dairy Products, dealing with the administrative aspect of the same subject, will appear in the Year Book.

ordinary milk. The highly potent concentrate as now produced from cod liver oil is diluted down to 150 D for two reasons: to have it in conveniently dilute form for measurement, and to avoid even the remotest possibility of accidental overdosage.

The milk produced in this manner has been frequently assayed on rats for antirachitic potency and has never been found wanting. This should be so, since the concentrate is standardized and the manner of incorporating is of the simplest kind. Studies have also been made of its antirachitic effect on infants. In children receiving about 100 to 150 units daily in milk, effects recorded in the healing of rachitic bones were the same as have been frequently shown with 3 teaspoonfuls daily of cod liver oil. Both X-rays and blood phosphorus showed a return toward normal in about 2 weeks, and cases of complete healing as judged by X-ray were recorded in about 40 days.*

The "vitamin D" milk made by the addition of a concentrate has certain characteristics which may distinguish it from other "vitamin D" milks.

1. It contains the "natural vitamin D," i.e. the same antirachitic substance we have always dealt with in cod liver oil. Steenbock¹ has recently presented evidence that the product made by artificial irradiation of sterols is not the same active substance as that occurring naturally in cod liver oil.

2. The rat assay data can be directly applied to human needs, avoiding the confusion and uncertainty we encounter in irradiated products. This is important, since all methods of standardization so far proposed involve the assay by means of rats.

3. The preparation of the milk is of the simplest kind, necessitating no extra equipment and not depending on special controlled feeding of cows. The chance of error is minimal, since only a simple measurement of a standardized, previously assayed concentrate is involved.

4. The price of the milk will, to begin with, be distinctly less than the price of ordinary milk plus the price of an equivalent amount of an average good cod liver oil. One dairy has been licensed to produce this milk, and the figures for cost are actual cost to consumer including all marketing and assay costs.

These facts are presented, not so much with a view to showing any relative superiority of one "vitamin D" milk over another, but rather for the consideration of the conditions under which one or the other milk may become a practical project.

If public health measures are to be instituted by means of "vitamin D" milk, a number of questions must receive careful consideration.

1. Can a milk of sufficiently constant potency be produced regularly in a dairy? The simplicity of the process involved in the incorporation of the concentrate in milk gives us relatively high assurance that errors can be avoided.

* These studies were made on 15 rachitic infants by Dr. Donald J. Barnes at the Children's Hospital in Detroit (in press).

Assays have been carried out on a considerable number of samples made under actual production conditions. These have uniformly shown the required number of units.

2. What is the most practical number of units of "vitamin D" per quart? We tentatively suggest 150 units per quart since this corresponds to the generally accepted dose of 3 teaspoonfuls of cod liver oil for any except very young infants, who would automatically receive smaller amounts in proportion to food intake. However, the number of units per quart can be so easily adjusted that any demand for other levels can be very readily met, if necessary, even by prescription.

3. Is there any danger either to the consumer's health or otherwise in putting this "vitamin D" milk on the market? Since we are dealing with the same antirachitic principle as has been used for many years in cod liver oil, there is no reason to believe that 150 units is either too high or too low. The effectiveness of the concentrate in various species (rat, chicken and man) is entirely parallel to that of cod liver oil. The small amount of cotton seed oil used as a solvent, diluted in the milk in the ratio of 1 to 12,000, is of no consequence. The question has been raised whether the introduction of "vitamin D" milk will discourage breast feeding, but there seems to be no very positive opinion one way or another. The possibility of encouraging self-medication is no more serious than that involved in the spread of knowledge concerning the beneficial effects of sunlight.

4. What does the project involve from the standpoint of enforcement agencies? The question has been raised whether the introduction of "vitamin D" milk will not put an undue burden on the officials entrusted with the enforcement of pure food laws or necessitate the establishment of large numbers of laboratories for biological assays. A cursory survey shows that in many states there are laboratories in state institutions (state university, agricultural college or experiment station) which are carrying on work of this type, and that such laboratories are increasing in number. There should be no difficulty in selecting in each state one institution to carry on the biological assays. To such designated laboratory the enforcement officials could forward the samples as taken up and receive a report in 12 to 14 days. The cost of these assays when done regularly and in suitable numbers is not as high as is commonly thought, and could be easily defrayed by the milk organization or the producer of concentrate without any significant increase to the consumer. As far as the pure food laws and the addition of foreign material to milk are concerned we should not rely on precedent such as acidophilus milk or chocolate milk but should allow this "vitamin D" milk to stand on its own merits. If it is not a useful project it should be rejected; if it is useful, the laws can be amended. In the meantime, wherever necessary, temporary permits such as are often granted will allow a thorough trial to be made as to usefulness and practicability.

NOTE: A plan of state supervision including biological assays at the State Agricultural College has in the meantime been put into effect in Michigan.

Nutritive Value of Cranberries*

CARL R. FELLERS, PH.D., F.A.P.H.A. (*Life Member*)

Massachusetts State College, Amherst, Mass.

AMONG the fruits, the cranberry is unique in several ways. It is among the last of the fruits to mature before winter, and because of its good keeping qualities is the only fresh berry available during the autumn and early winter. Normally the cranberry is consumed only after cooking. Cooked cranberries form a firm sauce or jelly with 40–45 per cent of sugar, whereas other fruits require from 65–70 per cent. The flavor and chemical composition also serve to differentiate the cranberry from other fruits.

The cultivated cranberry (*Vaccinium macrocarpum*) is grown principally in four areas in the United States: Massachusetts, New Jersey, Wisconsin, and Oregon-Washington. Of the annual crop of about 500,000 barrels or 50,000,000 pounds, Massachusetts produces about 65 per cent. The annual per capita consumption is approximately 0.54 lb. The active marketing season extends from September 10 to January 1, though cranberries are often available throughout the winter months. Approximately 65 per cent of the crop is sold through the American Cranberry Exchange—an outstanding example of a successful coöperative.

The cranberry grows in low-lying moist bogs or marshes and requires special soils and cultural treatment for successful growth. In Massachusetts there are about 14,000 acres of cranberries, the yield per acre averaging close to 25 bbls. The retail selling price is variable and depends upon the total production, but a fair average is 12 cents a quart (approximately 1 lb.). Though there are probably 50 varieties of cultivated cranberries, only a few are commercially important, among these being Howes and Early Black.

PROXIMATE ANALYSIS

The cranberry contains about 11.5 per cent dry matter of the composition shown in Table I.

Food Constituents of Cranberries—The sugars are relatively low, the acids high. According to Nelson¹ about 88 per cent of the fixed

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

acids are citric, the rest malic. Our data show a benzoic acid content of 0.035 to 0.095 per cent in 10 varieties—amounts that exert considerable preserving action on both the fresh fruit and manufactured products. Experience has shown that after filling the cans or jars with hot cranberry sauce, no further heat treatment is necessary.

TABLE I
COMPOSITION OF CRANBERRIES

| | <i>Per cent</i> |
|-----------------------------------|-----------------|
| Reducing sugars | 4.2 |
| Acids (citric, malic and benzoic) | 2.4 |
| Pectin | 0.65 |
| Fat and wax | 0.4 |
| Protein | 0.4 |
| Ash | 0.25 |
| Fiber, tannin and undetermined | 3.2 |
| Total dry matter | 11.5 |

Quinic acid, or a substance yielding quinic acid, is present to the extent of 0.6–0.9 per cent. This value was obtained indirectly by determining the total hippuric acid in the urine of young men on diets containing known amounts of cranberries. The benzoic acid in the berries was insufficient to account for the amount of hippuric obtained, hence the difference was assumed to be due to quinic acid. Recently Morse² has checked these results by more direct analytical methods. Great controversy has raged over the alleged harmful effects of small amounts of benzoates upon human health. In view of the simple method of elimination of benzoic acid from the body—conjugation with glycine to form hippuric acid, which is voided in the urine—the preponderance of scientific opinion, and our findings on young men fed up to 300 gm. of cranberries daily, support the view of the relative harmlessness of cranberries so far as their benzoic acid content goes. However, the recently discovered quinic acid is present in much larger quantities and, as Quick³ has proved, is transformed first to benzoic and finally to hippuric in a manner analogous to benzoic acid itself. The elimination of quinic acid from the body though slower, is usually complete in 12 hours. Blatherwick⁴ found that large doses of both prunes and cranberries increased the organic acids of the urine. Prunes produced twice as much hippuric acid as cranberries. The dose of cranberries fed was 300 gm., equivalent to almost 2 lb. of cranberry sauce.

Our data bearing on the effect of cranberries on urinary acidity and the blood alkali reserve are presented in Table II.

The hippuric acid in the urine is practically proportionate to the

TABLE II

| 300.0 | 27.5 | 2 | .42 | 3.60 | 46.5 |

weight of cranberries eaten though small doses affect the acidity very little. Similarly the pH of the urine was affected appreciably only after the administration of rather large quantities of cranberries.

The alkali reserve showed no decrease until more than 54 gm. of cranberries, equivalent to 5 oz. of cranberry sauce, had been eaten. Thus, usual, or even liberal servings of this sauce, do not appreciably affect the body's alkali reserve. The buffer action of the blood probably accounts for this protective action. Very large doses do produce significant transitory decreases in the blood alkali reserve.

Apparently the citric and malic acids present in cranberries are fully oxidized.

Other Constituents—Pectin is present in considerable quantity and is the constituent responsible for the high jellying power of cranberry sauce. The fruit must be cooked with boiling water to extract the pectin. Unlike other fruits the pulp or juice forms a firm jelly at a sugar content of 40–45 per cent.

TABLE III
NUTRITIVE PROPERTIES OF CRANBERRY SAUCE

| <i>Constituent</i> | <i>Mg. per 4-oz. serving</i> | <i>Constituent</i> | <i>Mg. per 4-oz. serving</i> |
|---|------------------------------|---|------------------------------|
| Reducing sugars | 48,590.0 | Copper oxide (CuO) | 0.4 |
| Fruit acids (as citric) | 916.0 | Phosphorus pentoxide (P ₂ O ₅) | 9.8 |
| Protein | 172.0 | Sulfur trioxide (SO ₃) | 5.3 |
| Fat and wax | 160.0 | Chlorine (Cl) | 1.7 |
| Total ash constituents | 107.0 | Iodine (I) | 0.002 |
| Fiber (whole fruit sauce) | 3,600.0 | Vitamin A | + |
| Potassium oxide (K ₂ O) | 33.0 | Vitamin B | — |
| Sodium oxide (Na ₂ O) | 3.4 | Vitamin C | ++ |
| Calcium oxide (CaO) | 10.7 | Vitamin D | — |
| Magnesium oxide (MgO) | 4.7 | | |
| Iron oxide (Fe ₂ O ₃) | 1.8 | Calories per 4 oz. serving | 200.0 |
| Manganese oxide (Mn ₂ O ₄) | 0.3 | Alkalinity of the ash | 2.2 |

The wax is present largely on the skins and acts to protect the fruit from water, insects and fungi. The protein content is low, about 0.4. The fiber, consisting largely of skins and seeds, is not objectionable in whole fruit sauce, and aids in elimination. The cranberry itself is mildly laxative.

The ash content is relatively low, but its reaction is definitely alkaline, in several varieties averaging 2.2. In spite of this some writers have stated that "prunes, plums and cranberries" are exceptions to the fruits that leave alkaline residues after digestion.

Table III shows the principal ash and other constituents as calculated from our analyses. Since the berries are seldom eaten raw, the figures are given in terms of a normal serving of cranberry sauce—1 lb. of cranberries yields approximately 2.6 lb. of sauce.

The ash constituents are largely potassium, calcium and phosphorus. Morse,⁵ and McClendon⁶ have determined the iodine content, which ranges from 26 to 138 parts per billion. This is relatively high for fruits and vegetables, and cranberries thus approach some marine foods in iodine content. The manganese content is likewise significantly high.

VITAMINS OF CRANBERRIES

The writer in collaboration with Isham has just completed a vitamin survey of cranberries. Only a summary of the results can be given here.

Using the Sherman, LaMer and Campbell⁷ technic, we found the vitamin C content of fresh cranberries in 1930 and 1931 to be relatively high—from 3 to 4 gm. daily sufficing to maintain normal growth and afford full protection from scurvy in 300 gm. guinea pigs. There

| " " | 3 | 1 | 8 | 3 | 90 | 4 |

was no varietal difference. The fresh fruit when stored for 3 months at 40° F. showed very little loss of vitamin C. Freezing and subsequent storage at 0° F. for 9 months did not affect the vitamin C content. However, alternate freezing and thawing had a very destructive effect. Evaporated whole cranberries contained no measurable amount of vitamin C, but a quick-dried powder or film retained over 50 per cent of the original C content. Cranberry juice is becoming a popular beverage. The fresh juice is fully as potent as the fruit, but after extraction, bottling, and processing, little of the vitamin C is retained by the methods now in use.

Whole-fruit cranberry sauce as usually prepared contains approximately 80 per cent of the original vitamin C content, but strained sauce retains less than 10 per cent.

Vitamins B and D were absent or present in such small quantities as to be insignificant. Vitamin G was present in traces only. Vitamin A was present in small but measurable amount—1.2 units per gm. This was sufficient to cure xerophthalmia in rats and produce normal growth.

SUMMARY

Aside from its esthetic values of eye and taste appeal, the cranberry is valuable in the diet chiefly for its high vitamin C, iodine, and energy values. The ash is slightly basic and contains significant amounts of potassium, phosphorus, manganese, and iron.

The benzoic acid content of fresh cranberries varies from 0.035 to 0.095 per cent and quinic acid from 0.6 to 0.9 per cent.

Moderate, or even generous servings of cranberry sauce do not lower the blood alkali reserve but very large quantities decrease it significantly.

The conjugation of benzoic and quinic acids in the body produce urinary acidities in proportion to the amounts of cranberry ingested, though servings of 5 oz. or less of cranberry sauce produce little change in either pH or hippuric acid values.

Fresh and frozen cranberries and whole-fruit jellied sauce are excellent sources of vitamin C and contain significant amounts of vitamin A as well. Vitamins B, D, and G are not present in significant amounts.

The cranberry possesses considerable merit as a food and when eaten in normal quantities its wider use in the diet can be recommended.

Industrial Medicine

A NEW illustrated journal of professional, scientific and public health interest, entitled "Industrial Medicine," made its appearance with Volume I, No. 1, October, 1932. It is devoted to the industrial interrelations of medicine, law, insurance, and economics, and aims at the cumulative study of these.

The journal contains articles, news items, reports, digests, and other presentations, together with editors' comments. The editorial policy is to encourage frank discussions and on this basis contributions are invited.

Issue No. 2, November, 1932, contains 75 pages. We note that 12 pages were devoted in this issue to a synopsis of pertinent papers presented at the Washington Meeting of the American Public Health Association.

Laboratory Diagnosis of Endemic Typhus and Rocky Mountain Spotted Fever*

L. F. BADGER, M.D.

P. A. Surgeon, U. S. Public Health Service, Washington, D. C.

THERE is widely scattered throughout the world a rather large group of diseases commonly referred to as the typhus-like group of fevers. The members of this group have many characteristics in common and are characterized in man by a sudden onset, chills, fever, severe headache, various degrees of prostration, mental symptoms, arthralgias and myalgias, and an exanthem. The viruses of several have been shown to produce agglutinins to *B. proteus* X₁₉. An insect vector has been incriminated epidemiologically in all and proved in some. Two members of this group, endemic typhus and Rocky Mountain spotted fever, occur endemically in the United States and the discussion in this paper will be confined to these.

THE experimental animals routinely used are the guinea pig, rabbit, and monkey, and the materials routinely employed in making inoculations are whole blood in spotted fever and whole blood and testicular washings in endemic typhus. Other materials may be used but those mentioned have been proved the most satisfactory.

The identification of a virus of endemic typhus or of spotted fever is based on the fulfilment of the following criteria: The clinical manifestations and pathological anatomy produced in animals by the unknown virus must be similar to those produced by the known virus; the production in the sera of rabbits and monkeys of agglutinins to *B. proteus* X₁₉; the production of a definite and complete cross-immunity between the unknown virus and the known virus. Cultures of the cardiac blood of animals from which inoculations are made should be negative.

THE DIAGNOSIS OF A VIRUS OF ENDEMIC TYPHUS

Clinical Manifestations and Pathological Anatomy—In the female guinea pig the only clinical manifestation is fever, while in the male

* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

an involvement of the external genitalia in addition to fever is the rule. The onset is abrupt after an incubation period varying with the material employed in making the inoculations. Generally the period of incubation is from 2 to 4 days following intraperitoneal inoculations with testicular washings, and from 6 to 10 days with blood or emulsion of brain tissue. The febrile response is irregular with a maximum temperature varying from 40.0° to 40.5° C. and a duration averaging from 6 to 7 days.

The most characteristic clinical sign of endemic typhus in the guinea pig is the involvement of the male external genitalia. This usually appears with the onset of fever, although it may appear a day or two before or after. The involvement is characterized by a diffuse erythema and edema of the scrotum, which may become markedly swollen and tense, and by an enlargement of the testicles which when well developed prevents them from being forced into the abdominal cavity. This condition gradually subsides and the tissues return to normal.

Macroscopically the appearance of the abdominal organs varies with the stage of the disease. For the first few days after onset the spleen is normal in appearance, while later it may be slightly enlarged and darker than normal with prominent Malpighian bodies. In the first day or two the testicles are swollen and the surrounding tissues are edematous with the vessels engorged. There is seen early a thin layer of exudate over the testicles. Hemorrhages may appear in the tissues, particularly at the poles. Later the tunica is thickened and adhesions develop.

Histological examination of sections of the brains of guinea pigs which have reacted to the virus reveals the vascular and nodal lesions seen in epidemic (louse-borne) typhus. These lesions, although less frequent than seen in some strains of epidemic typhus, have been found in approximately 25 to 60 per cent of the male* guinea pigs examined. The percentages have varied with the different strains of virus studied.

The clinical manifestations in the rabbit are indefinite. In a series of 69 male rabbits, 33 at no time had any evidence of fever, 15 had fever for 1 day, 6 for 2 days, and 1 had a fever lasting 3 days. None of the 69 showed any involvement of the external genitalia.

Monkeys react clinically with fever only. Eleven of a series of 13 monkeys responded to inoculation with a definite febrile reaction following periods of incubation of 1 to 4 days, with maximum temperatures of 40.0° C. to 41.3° C., the duration of the febrile periods

* Only male guinea pigs employed.

varying from 3 to 11 days. None of the monkeys showed evidence of an exanthem.

The mortality is nil in laboratory animals reacting to inoculations with an endemic typhus virus uncomplicated by secondary invaders.

The Weil-Felix Reaction—As a rule, the virus of endemic typhus produces agglutinins to *B. proteus* X₁₉ in the sera of rabbits and monkeys. In a series of 69 rabbits the sera of 52, or 75.3 per cent, gave complete agglutination (4+) in the titer of 1:80 or higher, and 32, or 46.3 per cent, in the titer of 1:160 or higher. The highest titer in which complete agglutination occurred was 1:640. The readings were made once weekly after inoculation and the maximum readings obtained with 7 on the 7th day; 46, or 66.6 per cent, on the 14th day; 14 on the 21st day; and 2 on the 28th day.

Of the 11 monkeys which reacted clinically, the sera of 8, or 72.7 per cent, gave complete agglutination in the titer of 1:80 or higher, and 6, or 54.5 per cent, in the titer of 1:160 or higher. The highest titer in which complete agglutination occurred was 1:640. The maximum readings were obtained from the 10th to the 20th day after the onset of symptoms with but 2 after the 14th day. All maximum readings were obtained after the temperature had returned to normal.

Cross Immunity—The guinea pig is the most satisfactory animal with which to carry out cross-immunity tests. Before one can state definitely whether or not an unknown strain of virus is one of endemic typhus, animals immune to the unknown must be tested with a virus of endemic typhus, as well as animals immune to the endemic typhus virus tested with the unknown.

Rickettsia—Rickettsiae are found in the tissues of the guinea pigs reacting to the virus of endemic typhus and in stained smears made with scrapings of the tunica.

THE DIAGNOSIS OF A VIRUS OF ROCKY MOUNTAIN SPOTTED FEVER

The virulence of Rocky Mountain spotted fever in the north-western states varies in different localities. In the Bitter Root Valley of Montana the mortality rate in the 12-year period, 1917–1928, was 76.8 per cent. In other sections of Montana the rate is around 30 per cent, and in Idaho around 5 per cent. In the states along the Atlantic Coast it has been from 20 to 25 per cent, resembling that in sections of Montana outside of the Bitter Root Valley. The difference in the virulence of the disease in the East and that in the Bitter Root Valley, noted in man, is also evident in laboratory animals. There is noted also a difference in the clinical manifestations in the guinea pig resulting from inoculations with the western virulent virus and the

eastern viruses studied, and which originated both from human cases and ticks infected in nature.

Clinical Manifestations and Pathological Anatomy—The febrile reaction in the guinea pig resulting from inoculations with the virus of the eastern type and of the western virulent type are essentially the same; however, there is a tendency for the incubation period to be shorter and the maximum temperature to be higher with the western virulent virus. Generally the period of incubation is from 1 to 4 days and the duration of the febrile period from 7 to 10 days with the maximum temperature from 40.5° to 41.5° C.

In the male guinea pig reacting to the western virulent virus involvement of the external genitalia is the rule, while such involvement is rare following inoculations with the eastern virus. Two strains of the eastern virus originating from human cases, and 1 originating from ticks infected in nature, have been studied in the male guinea pig. Involvement of the external genitalia has occurred only occasionally and attempts to transmit the involvement to subsequent generations have failed. This genital involvement is characterized clinically by erythema and swelling of the tissues of the scrotum. In a light colored animal the onset of the scrotal involvement has been noted as small reddish macules which become confluent and later hemorrhagic. Ulceration of the scrotum often occurs. If the guinea pig recovers the swelling subsides, the ulcers heal, and the tissues return to normal.

PHOTOGRAPH I—The appearance of the scrotum of a normal guinea pig

PHOTOGRAPH II—Scrotum of a guinea pig reacting to an intraperitoneal inoculation of a strain of *S. enteritidis*

The mortality rate in the guinea pig infected with the western virulent type is approximately 90 per cent, and that of the eastern type approximately 60 per cent.

On post-mortem examination during the early days of the disease the spleen is, as a rule, markedly enlarged, 3 to 5 times its normal size, smooth and darker than normal. With the viruses of the eastern type studied the testicles are normal, while with the western virulent virus they are enlarged and the surrounding tissues edematous. Later in the disease exudate may appear on the testicles and adhesions may form.

Histological examination of sections of brains of guinea pigs which have reacted to either the western virulent or the eastern virus reveals the presence of nodal and vascular lesions like those seen in typhus.

CHART I

CROSS IMMUNITY TESTS — DAILY TEMPERATURE RECORDS.

In the clinical manifestations in the rabbit there has been no difference noted between the western virulent and the eastern viruses. After an incubation period of 2 to 7 days, the rabbit becomes febrile, the febrile period varying from 4 to 10 days with a maximum temperature of 40.0° to 41.0° C. In the male there may occur an involvement of the external genitalia characterized by erythema and edema of the tissues of the scrotum and enlargement of the testicles. Ulceration of the scrotum may occur.

The apparent difference in virulence between the western virulent and the eastern virus is also noted in the monkey. Thirteen of 16 monkeys inoculated with the eastern virus reacted after periods of incubation of 3 to 8 days, while each of 15 monkeys inoculated with the western virulent virus reacted after periods of incubation of 1 to 3 days. The maximum temperature varied from 40.0° to 41.4° C. with the former, and 40.8° to 41.6° C. with the latter. All but 1 of the monkeys inoculated with the western virulent virus died, while but 2 of those inoculated with the eastern virus died. Eleven of the 15 inoculated with the western virus developed a definite exanthem in comparison with 8 of the 16 inoculated with eastern virus. In each instance the lesions first appeared over the brows and face in the form of rose colored macules. These lesions may become papular and purpuric or they may remain as macules. The lesions may be confined to the face or become general.

The Weil-Felix Reaction—The sera of 6, or 75.0 per cent, of 8 rabbits reacting to the western virulent virus gave complete agglutination with *B. proteus* X₁₉ in the titer of 1:80 or higher, while but 4, or 26.6 per cent, of 15 rabbits reacting to the eastern viruses gave complete agglutination in the same titer. The maximum readings were obtained in each instance in 7 to 14 days after the onset of symptoms. The maximum readings were also obtained after the temperature had returned to normal.

The maximum agglutination with the sera of the monkeys inoculated with the western virulent virus could not be determined as 14 of the 15 inoculated died in from 3 to 8 days after the onset. The production of agglutinins for *B. proteus* X₁₉ in the sera of monkeys inoculated with the eastern viruses is not constant. The sera of but 5 of 13 monkeys reacting clinically gave complete agglutination in the titer of 1:80 or higher.

The conclusion may be drawn that the production of agglutinins for *B. proteus* X₁₉ in the sera of rabbits and monkeys reacting to the viruses of Rocky Mountain spotted fever is not constant but when positive gives strong confirmatory evidence.

Cross Immunity—The procedures necessary to determine the immunological relation between an unknown strain of virus and a known strain of spotted fever virus are the same as those discussed in the diagnosis of a strain of endemic typhus virus.

Infections frequently occur spontaneously in guinea pigs and epizootics occurring among stock animals are not rare.

In undertaking to identify an unknown strain of virus suspected of being either typhus or spotted fever it must be borne in mind that known organisms may produce symptoms in laboratory animals, especially in the guinea pig, which cannot be distinguished clinically from those produced by these viruses. It has been found that clinical reactions produced by such organisms are particularly confusing when dealing with a virus, such as that of eastern spotted fever, which produces fever as the only clinical manifestation. Findings which could not be distinguished, either clinically or by the appearance of the abdominal organs, from those caused by the eastern type of spotted fever virus have been produced in guinea pigs by inoculation with a strain of *S. enteritidis*. To add to the confusion, this same organism

has produced occasionally in the guinea pig involvement of the external genitalia, which could not be distinguished clinically from that produced by a virus of endemic typhus. An illustration of this involvement is shown in photograph II.

On account of the confusing clinical reactions in guinea pigs the immunological relation between this strain of *S. enteritidis* and viruses of spotted fever and typhus was studied. In testing the immunity of recovered typhus and spotted fever guinea pigs to the *S. enteritidis* whole cardiac blood of guinea pigs infected with this organism was used. In each instance the *S. enteritidis* was recovered from the blood used in making the inoculations.

Twenty-seven guinea pigs immune either to the western virulent virus or the eastern spotted fever virus, with 49 fresh guinea pigs as controls, were inoculated with this strain of *S. enteritidis*. Seventy and three-tenths per cent of the immune animals failed to react (apparently immune), while but 8.1 per cent of the fresh controls failed to react.

Thirty-two guinea pigs, immune either to the endemic or epidemic typhus viruses, with 45 fresh guinea pigs as controls, were inoculated with this strain of *S. enteritidis*. Thirty-seven and five-tenths per cent of the immune animals failed to react (apparently immune), while but 6.3 per cent of the fresh controls failed to react.

When the immunity of guinea pigs immune to *S. enteritidis* was tested to the viruses of spotted fever and typhus different results were obtained.

Nineteen guinea pigs immune to *S. enteritidis*, with 32 fresh guinea pigs as controls, were inoculated with viruses of spotted fever. Ten and five-tenths per cent of the immune animals failed to react, while none of the fresh controls failed to react.

Seven guinea pigs immune to *S. enteritidis*, with 14 fresh guinea pigs as controls, were inoculated with typhus viruses. None of the animals failed to react.

Illustrations of this non-specific immunity are shown in Charts I and II.

Chart I—The male guinea pigs W 1737 and W 1754 were first inoculated with the virus of endemic typhus to which inoculations they reacted with fever and the characteristic scrotal involvement. They were later tested for immunity to the *S. enteritidis* (strain X). This immunity test was controlled by the inoculation of 2 fresh guinea pigs, WR 25-31 and WR 25-32. The 2 immune endemic typhus animals failed to react (apparently immune), while the control animals reacted.

Chart II—The guinea pigs TM 569 and TM 574 were first inoculated with the virus of spotted fever (eastern type) to which inoculations they responded with the characteristic febrile reaction. They were later tested for immunity to the *S. enteritidis* (Bacterium 190). This immunity test was controlled by the inoculation of 2 fresh guinea pigs, 190-21 and 190-22. The two immune spotted fever guinea pigs failed to react (apparently immune), while the control animals reacted.

In the charts the shaded portions represent fever, temperature over 39.6° C.

SUMMARY

There are certain and definite criteria for the identification of an unknown strain of virus as being one of endemic typhus or spotted fever.

With the exception of the involvement of the external genitalia of the male guinea pig the clinical symptoms produced in laboratory animals by the virus of endemic typhus exhibit nothing characteristic of the disease. In the male guinea pig the western virulent virus of spotted fever produces a characteristic involvement of the external genitalia, while the viruses of the eastern spotted fever studied produce no symptoms in the guinea pig which are not produced by some known bacteria. Both the western virulent virus and the eastern virus of spotted fever may produce in the rabbit the characteristic involvement of the external genitalia and in the monkey the characteristic exanthem.

The viruses of spotted fever, as well as the virus of endemic typhus, produce in the brain of the guinea pig the nodal and vascular lesions seen in European louse-borne typhus.

The Weil-Felix reaction has been found positive with approximately 75 per cent of the sera of rabbits and monkeys inoculated with either the endemic typhus virus or the western virulent spotted fever virus. The Weil-Felix reaction has been found positive with but approximately 25 per cent of the sera of monkeys inoculated with the eastern spotted fever virus.

Immunity tests must be clean-cut and made in both directions.

Cultures of the cardiac blood of animals from which transfers are made must be consistently negative, as confusing clinical symptoms and immunity tests have been caused by known bacteria.

Statistics and the Health Officer

GEORGE B. L. ARNER, PH.D.

U. S. Bureau of the Census, Washington, D. C.

IT is not my purpose to review the rise and progress of preventive medicine. It is enough to say that with the concentration of population in the new industrial cities there came the beginning of sanitation. Then in the last half of the 19th century came the brilliant discoveries of Pasteur, Koch, and a host of other scientists, which now form the basis of the efficient work of the modern health officer.

The record of these triumphs of sanitation and preventive medicine is the subject matter of vital statistics. Vital statistics are inseparable from preventive medicine just as accounting is inseparable from modern business. Without vital statistics the health officer, the modern public health administrator, would be working in the dark. He would have no means of measuring the degree of his success or failure. In a small village where the health officer knows every person in town and where he personally attends to the suppression of nuisances and the enforcement of quarantine, he may not feel the need of vital statistics. His statistics may be kept in his head, and he is not aware that they are statistics. The city health officer, however, is the executive head of a public health organization, and as such he must depend upon statistics as the business executive must judge the state of his business by his accounts and his statistical charts.

The health officer does not need to be a vital statistician, any more than a business man needs to be an accountant, but he should be able to understand vital statistics and to use them effectively in his daily work. He should know the uses and the limitations of every device used in vital statistics, although he may depend upon his statistician to compute even the crude death rate and the infant mortality rate.

The health officer is interested in vital statistics from two standpoints: first, in his capacity as local registrar, as the source of the original data; and second, in his capacity as a public health administrator in which he is one of the chief consumers of the product.

The value of vital statistics depends upon the accuracy and completeness of the original observations, for which the local registrar

* Read before the Health Officers Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

is responsible. For the finished statistical product, the statistician is responsible. He must reduce this mass of disconnected observations into the usable form of tables, rates and trends, which are sensitive indices of public health and social conditions. If properly prepared and properly understood and used, these results are an accurate guide to the work of the health officer. Improperly prepared or misused vital statistics may be very misleading.

Statisticians, and those who make use of statistics, are no better and no worse than professional men in other fields. It is one of the reproaches leveled against the medical profession that experts may be obtained to testify on either side of a personal injury case. It is also possible to twist statistics in such a way as to deceive the uninitiated.

At the recent convention of the American Bar Association in Washington, Dean Roscoe Pound told the story of the experience of the Wickersham Commission in the field of statistical analysis. It seems that the Commission had accumulated a vast quantity of undigested material bearing on the subject of their investigation and found that before this material could be used it would have to be boiled down and analyzed by approved statistical methods. The Commission searched far and wide for the highest powered statistician available, and when they had found the man who met the requirements, they presented him with the mass of material and told him to go ahead. The eminent statistician, however, shifted his cigar to the other side of his mouth and asked: "Now, gentlemen, what is it you would like to prove?"

Statistics, like the Holy Scriptures, are usually accepted on faith, and they lend themselves readily to the spreading of false doctrine. The devil can quote Scripture, and the booster, the propagandist, the high pressure salesman, and the unscrupulous advertiser can prove anything by statistics.

Vital statistics, as well as economic statistics, lend themselves readily to the use of the professional booster and to the health officer whose chief interest is his own self-glorification. The public is now thoroughly sold on the advantages of sanitation, and newspaper readers generally have a dim idea that the death rate is a measure of the health of the community. They do not, however, appreciate the refinements of vital statistics. The health officer should understand and correctly interpret the findings of the statistician. For example, the crude death rate is frequently misused by those who do not understand its shortcomings. The crude death rate is easy to compute and readily understood, and is very useful within proper limits,

but beyond those limits it may be grossly misleading. For comparisons between cities or between any two areas of different social composition, it is often improperly used. In a rapidly growing city, the professional booster may call attention to the low death rate of his community as compared with that of some older, slowly growing city. It may be true that there are very few deaths in his city per 1,000 of the population, but it may also be true that many persons who are ill are taken to the hospital in the older community and die there, so that their deaths are not registered in the place of their residence. It may also be that in the rapidly growing city the population is highly selected, with few old people and few very young children. In order to make an honest comparison of death rates between one community and another, the death rate must be adjusted for residence and corrected for age. The adjustment of death rates for residence, as well as the adjustment of birth rates by residence of the mother, can only be made if the information as to residence is accurately stated on the death and birth certificates. The adjustment for residence is often very great, especially in small cities having large hospitals. In Rochester, Minn., for example, the crude death rate in 1929 was 50.4 per 1,000 of the population. Adjustment for residence reduced this rate to 15.7, or less than one-third. The correction for age is particularly important in rapidly growing industrial cities. The crude death rate in Detroit, for example, is much lower than that in Columbus, O., but after correction for age, the refined rates are found to be almost identical.

A classic example of the misuse of crude death rates is found in the frequently quoted statement that as a result of the work of General Gorgas and his assistants the death rate of the Panama Canal Zone was reduced to less than the death rate in the United States. In a speech at Charleston, S. C., December 16, 1915, General Gorgas made the following statement:

We had on the Isthmus some 10,000 American whites, about one-half of whom were men and the other half women and children. The children were equal in number to the women. The health of these whites was exceptionally good. During 1913 the death rate among the men from disease was about 2.5 per thousand, that among the women and children about 4 per thousand. It would be difficult to find anywhere in the United States in a similar population death rates better than these.

The achievement of the health administration in the Canal Zone in transforming a tropical pest hole into a region in which women and children could live and in which white men could work, did not need any exaggeration, but such statements as those quoted above,

repeated without qualification, are grossly misleading. The facts were that this population was probably the most highly selected group of its size ever brought together in one health administration area. There were no old people and few very young children. All were in the age periods characterized by very low death rates, and furthermore every one who became ill was sent as quickly as possible back to the United States, so that the deaths in the Canal Zone were only those from acute attacks of disease from which death occurred before the patient could be transferred out of the Canal Zone. By 1930 the crude death rate in the Canal Zone had been further reduced to less than half the rate of 1913, but the government even now discourages permanent residence and the report for 1930 of the Health Department of the Canal Zone states that practically all who retire from the service either from disability or age return at once to the United States.

The health officer in the course of his routine work may make use of the crude death rate for the comparison of one month or one year with another in the same area, but for a comparison of different areas, or the comparison of his city with another city, the rates must be adjusted for residence and corrected for age.

For further analysis in large areas, the death rates must be shown for different ages and for different causes of death. These are known as specific rates. Age-specific death rates are shown as the number of deaths of persons of a given age or age period per 1,000 of the population of the same age or age period. Age-specific death rates are high in infancy, low in childhood and in early adult ages, and are very high again in old age. The health officer is mainly interested in the death rates of childhood and middle life. Deaths beyond the age of 50 are usually from degenerative diseases which are largely beyond the control of public health administration.

Specific death rates by cause are usually expressed as the number of deaths from any cause per 100,000 of the population. These rates are sensitive and are particularly valuable as a guide to epidemiologists. Attention can be concentrated on preventable causes, and the trends measured from week to week. Here again comparisons between areas are dangerous without correction for age and residence. The specific death rate from diphtheria, for example, will ordinarily be higher in an area in which 20 per cent of the population is under the age of 10 than in a population with less than 10 per cent in the early age periods.

Infant mortality may be shown as an age-specific death rate for children under 1, or better by a ratio of infant deaths to total live

births. There is no single index of progress in public health more sensitive or more significant than the infant mortality rate based upon the ratio of infant deaths to births. In the good old days before germs were discovered, the mortality of infants was frightful according to modern standards. High as birth rates were in past ages, infant mortality kept the population about stationary. In many communities, less than half of the children born survived their first year. As recently as the generation in which most of us were born, there were more than 150 infant deaths to 1,000 births. In Massachusetts, the infant mortality rate first fell below 150 in 1897. In 1901 it was 138, and in 1909, 127. In 1917, for the first time, the rate was below 100, and in 1931 it was 56. For the entire registration area of the United States the infant mortality rate in 1931 was 62. This rapid reduction in infant mortality is an achievement which can never be duplicated again, for an analysis of infant deaths by cause will show that there are so many deaths from causes which cannot be prevented that infant mortality rates below 40 per 1,000 births cannot be expected except in limited areas in occasional years.

The computation of infant mortality rates depends upon an accurate record of births. The health officer, in his official capacity, may not be directly interested in births, but indirectly his record of births is of greatest importance to him. As has been noted, the number of births is necessary for the computation of the infant mortality rate, and in a general sense he is interested in births as the source of renewal of the population and in the changing birth rate as a means of forecasting the age composition of the population of the future. The crude birth rate, like the crude death rate, is calculated as the number of births per 1,000 of the population. A more accurate measure of the fertility of a population is a refined birth rate obtained first by adjusting births to the residence of the mother and basing the computation not on the population as a whole but on the number of women between the ages of 15 and 45. Still better is the legitimate birth rate based on the number of children born per 1,000 married women between the ages of 15 and 45.

The rapid decline in the birth rate in recent years is as significant as the decline in the death rate. In the "Good Old Days," now happily gone forever, the fate of a married woman was to give birth to a child every year or two until she was worn out and obliged to surrender her place to wife number two. Of 8 to 15 children, perhaps half were "raised" to maturity. The birth rate was probably around 40 per 1,000 and the death rate almost as high. As recently as 16 years ago the crude birth rate in the registration area of the United

States was 25 per 1,000. In 1931 it was 17.8, and it is expected that for 1932 the rate will fall below 17. This is startling enough in itself, but it does not tell the whole story. Because of immigration and the relatively high birth rates of a generation ago, our population in the reproduction age periods is abnormally large. This abnormal age distribution permits the low death rates of recent years, and under ordinary conditions should show a high birth rate. If we make corrections for age, we will find that with births and deaths as they will be recorded for 1932 the completely refined death rate will be higher than the refined birth rate. This means that present refined birth and death rates continue until persons now in middle life become old, the population of the United States, instead of increasing, will begin to decline. The sudden and dramatic change in one generation from a rapidly increasing population to a stationary or a declining population is hard to realize.

With a continuance of present trends, the social problems of the next generation will be vastly different from those of the past. There will be fewer children and more old people, fewer schools and more homes for the aged, fewer deaths from epidemic diseases and more from degenerative diseases. The death rate, now the lowest ever known, will rise again until it reaches the rate of 30 years ago. This rising mortality will be beyond the control of preventive medicine, for the deaths will be from causes which only a fountain of youth can prevent.

The prospect of a stationary population is very alarming to those who fear change, but after all, will it not make for a happier and more prosperous world? Business conditions will become more stable. The needs of the population can be more readily calculated. Social planning will become more practicable. There will be less speculation, particularly in real estate, and less of the ballyhoo of the professional booster.

In the "Good Old Days" we were fatalists. Our attitude was typified by the familiar words "The Lord giveth and the Lord taketh away, blessed be the name of the Lord." In the future the Lord will be relieved of that terrible responsibility. Children will come when they are desired and when born will live out the allotted span of "three score years and ten." Without realizing it, we are moving toward the ideal of a controlled population. The population need not decline. Economic sanctions can be devised which will maintain the birth rate at any desired level. Until some way is found to check the degenerative changes of advancing age, little more can be done to reduce the death rate. The birth rate on the other hand is capable

of reduction to the vanishing point, but at the same time it is responsive to economic conditions.

More than any other person, the health officer is interested in all that vital statistics has to offer. It is on the health officer as registrar that the vital statistician depends for the complete record of births and deaths. The health officer in turn needs vital statistics as a guide to his work and a record of progress. We should not flatter ourselves that all the gains of preventive medicine are secure. Only constant vigilance prevents the return of epidemics against which our population may be losing its immunity. The health officer must use and properly understand the uses and limitations of all the devices of vital statistics, and he should have the benefit of the forecasts of future conditions in his field, which the vital statistician alone can give him.

Maternity Leave in Denmark

THE Danish Women Workers' Union, composed of about 12,000 members, recently adopted a resolution to the effect that the Government and Parliament should be urged to guarantee women workers the payment of their wages in full during a rest period of 6 weeks before and 6 weeks after confinement. At present, women workers in Denmark are entitled to 4 weeks' rest after confinement, together with an allowance payable from public funds, on presentation of a medical certificate, requiring such a rest period.—*Industrial & Labour Information*, XLIV, 6:177 (Nov. 7), 1932.

E. R. H.

Study of Bacteriological Methods of Testing and Means of Disinfecting Water with Chlorine

With Particular Reference to Swimming Pool Water*

W. L. MALLMANN, PH.D., AND WILLIAM CARY, JR., F.A.P.H.A.

*Department of Bacteriology, Michigan Engineering Experiment Station,
Michigan State College; and Detroit Department of Health,
Detroit, Mich.*

SINCE the adoption of continuous feed chlorination of swimming pool water whereby residual chlorine contents of 0.2 to 0.5 p.p.m. may be maintained irrespective of the bathing load, bacterial quality comparable to drinking water has been obtained. In 1926, Stovall, Nichols, and Vincent¹ reported that the relationship between the bacterial purity of the water and the residual chlorine content as measured by the orthotolidine test was so satisfactory that this test could be depended upon as a measurement of sanitary quality. In the same year Mallmann² observed such a close agreement in the bacteriological and the orthotolidine tests that he recommended the latter as the sole measurement of the sanitary quality of swimming pool water. Since then numerous reports have appeared showing the absence of *Escherichia coli* in 50 c.c. of water in swimming pools maintaining a residual chlorine content of 0.2 to 0.5 p.p.m. There has been no occasion to question the reliability of these data, until recently in a series of studies on swimming pools, the writers had occasion to test swimming pool water immediately after it was withdrawn from the pool. In 1930, Schoepfle³ reported that pool side bacteriological tests and tests on the same stored samples tested later at the laboratory were practically the same. He concluded that

. . . the increment of pollution to the pool water due to swimmers seemed to be handled effectively by maintaining the residual chlorine within proper limits;

* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

this sterilizing action on the added pollution by bathers seemed to be practically immediate, at least within the time required for making a rapid plating and tubing, that is approximately one minute.

In a recent series of studies Mallmann and Schalm⁴ have demonstrated that increased alkalinities in water cause a marked retardation of germicidal action of chlorine. Gerstein⁵ found that chloramine could not be used as a disinfectant in Chicago water because of delayed germicidal action. The fact that this latter treatment, because of its lessened taste and odor nuisances, is rapidly finding favor in swimming pool disinfection, and the establishment of delayed killing action of chloramine and of chlorine in alkaline waters, raised the question of their sanitary value for swimming pools. The sterilization of a swimming pool water is quite different from that of a drinking water. In swimming pool water disinfection the residual chlorine must destroy large numbers of bacteria as they are removed from the bodies of the bathers; otherwise during periods of heavy bathing loads, an accumulation of bacteria would occur and, at least, a temporary period of pollution would ensue.

To study the influence of chlorine and chloramine treatment without the interference of such other factors as filtration and dilution, a fill and draw pool of 45,000 gallons capacity was selected. An attempt to use a circulating system pool gave unsatisfactory results as the circulation introduces factors that are difficult to control. Furthermore, chloramine had not been used in a pool with a circulating system prior to the experiment and the possibility of the filters removing the ammonia lends another unknown factor. There is also some question as to whether or not the ammonia, when once introduced into a closed system such as a circulating system pool, would remain available for further combination with chlorine after it had released its initial load for sterilization purposes. Available data indicate that in such a closed system after the initial treatment with an ammonia-chlorine ratio of 1 to 2 or 1 to 3 subsequent treatments can be reduced to 1 to 10.

To determine the necessity of pool-side testing a bacteriological laboratory was set up in the school readily accessible to the pool. For each test two samples were collected simultaneously, one of which was tested immediately while the other was kept and tested several hours later at the city laboratory. The latter was handled in a manner typical of the customary routine. In Table I are presented results representative of a mass of data collected to measure the comparative

TABLE I

VALUE OF POOL-SIDE TESTING VS. REGULAR LABORATORY TESTING

Pool—45,000 gal. capacity—fill and draw type

Treatment—Chloramine

| | | |
|-----------|-------------|----------|
| Bathing — | 9:30– 9:50 | 30 men |
| | 10:15–10:35 | 37 men |
| | 1:15– 1:35 | 12 women |

| Time of sampling. | Resid. Cl. | Analyses at pool side | | Analyses at laboratory | |
|----------------------|---------------|--------------------------------|-------|--------------------------------|-------|
| | | Gas in five 10 c.c. samples | Count | Gas in five 10 c.c. samples | Count |
| 9:25 | 0.15 | 0 out of 5 | 0 | 0 out of 5 | 0 |
| 10:25 | 0.18 | 5 out of 5 | 65 | 0 out of 5 | 0 |
| 10:50 | 0.05 | 5 out of 5 | 34 | 0 out of 5 | 0 |
| 1:00 | 0.25 | 0 out of 5 | 19 | 0 out of 5 | 0 |
| 1:30 | 0.25 | 4 out of 5 | 22 | 0 out of 5 | 0 |
| 2:30 | 0.25 | 0 out of 5 | 0 | 0 out of 5 | 0 |

value of pool-side and the customary laboratory examinations. In this particular series of tests, the pool received 3 oz. of chlorine and 1.5 oz. of ammonia, a ratio of 2 to 1, prior to the tests. The pool had been previously emptied and cleaned so it was free of organic matter at the start of the experiment. It will be observed that in each case during the period when the pool was in use, marked pollution, as measured by gas production in lactose broth, was obtained in the pool-side samples. The same samples tested at the laboratory in every instance showed no evidence of pollution. In cases of minimum bathing loads and of high residual chlorine contents (0.5 to 1 p.p.m.) pool-side tested samples failed to show pollution. Thus it would seem that under proper conditions, as pertain to bathing load and amount of residual chlorine, a pool can be maintained according to the standard set by the Joint Committee on Swimming Pools and Bathing places of the American Public Health Association and the Conference of State Sanitary Engineers when examined by pool-side testing.

That such a method of testing is logical, is attested by the fact that the presence of even a minimum chlorine residual indicates the presence of germicidal chlorine. If germicidal chlorine is present, it necessarily follows that any bacteria present are going to be affected accordingly. If a period of time elapses between sampling and testing, a reduction of the bacteria must result. Granted a sufficient period and a sufficient amount of residual chlorine, an otherwise polluted sample would be sterile when tested.

In the following studies only the results of pool-side testing will be

reported as, in practically all cases, the samples tested at the laboratory were sterile. Also the presence of streptococci will be reported. The regular Durham lactose broth tubes were examined for the presence of these organisms. The method of detecting streptococci consisted of a macroscopic examination followed by a confirmatory microscopic examination. Macroscopically, a presumptive test for streptococci may be made by holding the suspected tube to the light and examining for a granular precipitate having a close resemblance to the precipitate obtained in an agglutination test. Frequently, a granular floc adheres to the outer sides of the tube and on the outer surfaces of the inverted vial. Although the appearance of the granular precipitate is not always confirmed microscopically, the absence of such granular precipitates does not demand microscopical examination.

Mallmann and Schalm⁴ demonstrated in a series of laboratory experiments that increasing alkalinities caused a decreased activity or delayed killing action of chlorine. It will be observed that at the same pH values, a marked similarity exists between chlorine and chloramine in the germicidal activity. That increasing pH values cause a decrease in the germ killing speed of chloramine, as well as chlorine, is demonstrated in Figure I. It will be noted that at pH 6, the killing rate is much more marked than at pH 7.7.

To determine the practical value of chloramine treatment, a fill and draw pool of 45,000 gal. capacity was treated with chloramine using calcium hypochlorite and ammonium sulphate as sources of chlorine and ammonia respectively. Prior to the experiment the pool was emptied and cleaned. One ft. of water was admitted, followed by 12 oz. of ammonium sulphate. After another ft. of water was added, 6 qt. of calcium hypochlorite solution (20 lb. to 20 gal. of water) was introduced. The pool was then filled. The applied chlorine was in the proportion of 1 p.p.m. and the ammonia-chlorine ratio was 1 to 2. Frequent duplicate samples were taken throughout the day during periods of use and rest to obtain a complete picture of the bacterial pollution. One set of

FIGURE I—Influence of varying the pH on a constant chloramine content in killing *E. coli*

samples was tested immediately after collection. The results are presented in Figure II. It will be observed that the colon bacilli indices rise during the period of use and fall during the intervening rest periods; that the streptococci indices follow the same trend as the colon bacilli indices, except that streptococci are less frequent; that the residual chlorine content remains fairly constant although no additions of chlorine were made during the period of the test. During the rest periods between bathing loads, sterilization was not effected although a fall in colon bacilli and streptococci indices is evident. In considering these data it should be remembered that the other set of samples collected in the usual manner and tested later in the city laboratory without exception failed to show either streptococci or colon bacilli in all tubes. It may be concluded from these data that 0.5 p.p.m. available chlorine as chloramine failed to control pollution as measured by colon bacilli and streptococci indices.

The following day, after emptying and cleaning the pool, chlorine treatment was tested under as nearly identical conditions as possible. The pool was treated with 6 qt. of calcium hypochlorite solution (20 lb. to 20 gal. of water) to give an applied dosage of 1 p.p.m. At the start of the experiment the pool had a residual chlorine content of 0.45 p.p.m. The data are presented in Figure III. A similar set of data was obtained during periods of rest, except that greater and sharper falls in pollution indices were obtained. The streptococci and colon bacilli indices follow the same trend; the streptococci, how-

FIGURE II—Relationship of pollution, chlorine residual contents, and bathing load in a chloramine treated swimming pool

ever, having a lower incidence. The residual chlorine content fell rapidly and it was necessary to make additions to keep it above 0.2 p.p.m.

It will be observed that as the residual chlorine content falls a marked increase in colon bacilli and streptococci indices occurs. Recovery after pollution was always very rapid. In other tests not presented, under conditions as above, sterility generally occurred within 10 minutes after the bathers had left. This was not true with chloramine treated pools or chlorine treated pools with alkalinities of pH 8.

In the studies cited, the incidence of colon bacilli was considerably higher than that of streptococci. That this relationship is not always true is shown in Tables II and III. These samples were obtained

from a 260,000 gal. out-door pool with a recirculation system. In Table V, are shown the results obtained on successive days, using chloramine treatment and chlorine treatment with residual chlorine contents of 0.1 p.p.m. in both cases. All samples were collected during periods when the pool was in use. Although the numbers of colon bacilli were far less in the case of chlorine treatment there was no change in the incidence of streptococci. Table III gives

the data obtained from the same pool using 0.6 p.p.m. available chlorine in the case of both chlorine and chloramine.

In this case, colon bacilli were absent from the chlorine treated water and a marked reduction in the number of streptococci occurred. It may be stated, however, that both colon bacilli and streptococci follow the same trend as a measurement of pollution in a chlorinated pool. Their relative relationship as to numbers apparently varies. Insufficient data on this particular point make any explanations impossible.

The writers are not prepared to weigh the significance of the colon bacilli and streptococci as found by means of the pool-side testing during periods of use of the swimming pool. Whether or not the pollution found has any sanitary significance remains to be seen. It is true, however, that the usual method of testing, whereby samples are held for a period of time between collecting and testing, does not give a true picture of the sanitary quality of a swimming pool. Such methods of testing as are now in general use are to be condemned as giving a false sense of security if we are to consider the presence of the colon bacilli and streptococci as a criterion.

The disappearance or loss of residual chlorine varies with the conditions under which the chlorine is introduced. A number of investi-

gators have reported that chloramine treatment stabilizes the residual chlorine content. To obtain confirmatory data upon this point, residual chlorine contents were observed under 3 conditions, namely, high alkalinity (pH 7.3–7.9), neutral reaction (pH 6.8–7.2), and chloramine treatment (pH 7.2). The data are presented in Table IV. In the case of the chloramine treatment, although only an initial dose of calcium hypochlorite was made, the residual chlorine content remained practically constant. With chlorine treatment at pH 6.8 to 7.2, 33 per cent more chlorine was necessary to retain a minimum dose in excess of 0.2 p.p.m. available chlorine with a considerably smaller bathing load. With chlorine treatment pH 7.3 to 7.9, the chlorine loss was not as great as pH 6.8 to 7.2 but more so than with chloramine treatment. However, although delayed killing action occurred, the extent of pollution during periods of use was far less than with chloramine treatment. On the other hand, the chloramine treated pool with an average residual chlorine content of 0.45 p.p.m. showed marked pollution during periods of use as measured by pool-side testing. The stability of chlorine residuals in chloramine treated pools has little value if the sanitary quality of the pool is sacrificed. Examination of 3 chloramine treated pools with chlorine residuals of 0.1 to 0.6 p.p.m. has failed to show the desired sanitary quality as measured by pool-side testing.

FIGURE III—Relationship of pollution, chlorine residual contents, and bathing loads in a chlorine treated swimming pool

STABILITY OF CHLORINE IN ALKALINE CHLORINE, NEUTRAL CHLORINE AND CHLORAMINE TREATED POOLS

[illegible]

The writers feel that the present method of sampling should be supplanted by a method of pool-side testing. Pool-side testing is, of course, out of the question as a routine procedure, but a method of collecting samples in sodium thiosulphate treated bottles makes possible the elimination of the residual chlorine so that the sample can be transported to the laboratory without destruction of the bacteria.

The bottle is prepared by adding a small crystal of sodium thiosulphate to a moist bottle or 0.5 c.c. of tenth normal sodium thiosulphate to a dry bottle subsequent to sterilization by moist heat. Care must be taken not to rinse the bottle in collecting the sample. The sodium thiosulphate added is sufficient to neutralize a residual chlorine content of at least 1 p.p.m. The results obtained from sodium thiosulphate treated bottles and from pool-side tested samples are similar.

Samples collected from chlorinated swimming pools should be taken during use to determine the presence of transient pollution. Samples taken during periods of rest will, if collected 15 to 30 minutes after use, generally fail to show pollution. All samples should be collected in sodium thiosulphate treated bottles.

The building up of pollution in the swimming pool in the presence of residual chlorine would seem to indicate that bathing loads should be regulated to avoid excessive pollution. The view that the presence of residual chlorine indicates the absence of bacteria must be revised.

Further work on this phase of the problem is in progress in a number of swimming pools in Detroit and Lansing.

This report is very largely of a preliminary nature and will be followed by reports on more complete studies.

SUMMARY

1. Samples of swimming pool water collected during periods of use and tested immediately showed more pollution than duplicate samples handled in the usual manner by storing and testing later.

2. During periods of use, swimming pool water showed marked pollution as measured by colon bacilli and streptococci indices in the presence of residual chlorine contents of 0.2 to 0.5 p.p.m.

3. During periods of rest, the pollution evidenced during use, disappeared. The rate of disappearance depended upon the type of treatment used.

4. With chloramine treatment, a delayed germicidal action occurred. This was also true of chlorine treatment in alkaline water, but to a lesser extent.

5. The colon bacilli and streptococci indices roughly parallel each other. The preponderance of the colon bacilli and streptococci incidences varies.

6. A sodium thiosulphate treated sample bottle is recommended for collecting pool samples.

PREVENTION OF RICKETS

THE prevention of rickets is a very live question in spite of the fact that with direct irradiation, ultra-violet rays, cod liver oil or its concentrates, Haliver oil, viosterol, activated milk, etc., we have more specifics for it than for any other single disease. It is, however, extremely prevalent, even in quarters where it would be least suspected.

There is a growing feeling that some form of antirachitic milk is the best preventive as well as curative, since it has the marked advantage of a high content of calcium and phosphorus. Another point which has been brought out before, but was emphasized by several speakers in the recent symposium at our 61st Annual Meeting, is that the results of standardization of antirachitic agents as units per c.c. or per quart, does not accord with clinical experience. Much more viosterol is needed to protect infants than would be expected from the assays on rats. Several of the speakers, led by Hess, pointed this out. There is no doubt that the estimation of human dosage on the basis of rat assays is fallacious when compared with clinical results, though until the work of Hess and Lewis appeared, these biological assays entirely overshadowed clinical data, which after all constitute the essential criterion.

There are a number of ways of increasing the antirachitic potency of milk. One which seems to be favored by Hess¹ above others is the feeding of activated yeast to the milch cows. He considers it

especially applicable to certified dairy farms, since one can be sure of the quality of the yeast used, the ration fed, and frequent biological assays of the milk. For the general supply of large communities, the method does not seem applicable at present. However, irradiation of the milk can be carried out at a central station. An exposure of 16 seconds to certain carbon arc rays is sufficient for the purpose, and this does not develop any bad odors or tastes, nor are the vitamins injured. Extensive experiments over two winters in New York has shown that such irradiated milk will prevent rickets practically without exception, even in negro infants, who are particularly susceptible. The amount of milk fed these infants was only $2/3$ quart daily, instead of the quart usually recommended.

Hess further points out that laboratory experiments show that a greater number of antirachitic units are required when viosterol is given than when cod liver oil is used, and has suggested that in addition to vitamin A, cod liver oil contains something of value against rickets which is not present in irradiated ergosterol. He believes that we should be guided by the clinical activity of our antirachitic agents instead of depending too much upon the laboratory assay. He supports strongly the use of activated milk, fluid or dry, since it has the advantage of providing an automatic method for the prevention of rickets, supplies the essential factor in a medium rich in phosphorus and calcium, and the results are obtained by means of an exceptionally small amount of the antirachitic factor.

Another paper² given in the symposium reported on milk irradiated with the carbon arc lamp, milk from cows fed irradiated yeast, and from cows irradiated directly with the carbon arc lamp. The results were closely comparable with these obtained by Hess. Clinical studies on infants in a large foundling home over a period of nearly 8 months were entirely satisfactory, and in two other hospitals, children with marked rickets were treated with prompt cure in every instance.

The direct irradiation of cows with the carbon arc lamp is carried out by placing a lamp between pairs of cows so that only one side of the udder and abdomen are irradiated. The type of lamp used is the same as for the direct irradiation of fluid milk. The experiment so far has included 50 cows. Each was irradiated for 15 minutes daily, and the treatment was begun 2 weeks before the milk was used. These experiments have gone on for 9 months. The results on 21 infants over a 6- to 8-month period practically parallels those produced by irradiated fluid milk. The authors believe that irradiation of the cow has certain advantages over the irradiation of fluid milk,

and that it can be used not only in herds producing certified milk, but those of smaller communities. They also believe that it is considerably cheaper than other methods for institutions which care for a large number of infants.

Another paper³ in the symposium gave the results of experiments which have been going on at Columbia University for several years; namely, the purification and improvement of a concentrate from cod liver oil which contains the antirachitic element. This concentrate, in the proportion of 1 part to 12,000 of milk, will give practically 150 units of vitamin D per quart, equivalent to 3 teaspoons of cod liver oil. The concentrate may be added in several different ways, but the one apparently preferred by Zucker is to add it to the cream, pasteurize the milk, and recombine the two. Only 15 experiments on rachitic infants have been carried out by this method so far, but the results were entirely favorable and comparable to those obtained by a dosage of 3 teaspoons per day of cod liver oil. The author believes that this offers perhaps the best and safest method, since the concentrates are carefully assayed, and there is no possibility of accidental overdosage. So far, one dairy has been licensed to produce such milk, and the additional cost is said to be 1/25 cent per quart.

Some authorities object to what they call doctoring milk, and at present the addition of foreign material will probably meet with some opposition from the authorities carrying out the pure food laws, but if it is shown to be better than other methods, these laws can be changed.

This symposium contains much food for thought, and through the labors of these experts, we have learned of a practical method for the prevention of the widespread disease, rickets.

MOTTLED ENAMEL

WE wish to call attention to a situation in connection with public health activities which in some respects has unique features. Some years ago it was found that the permanent teeth of all the children born in Chetopa, Kansas, were afflicted with what is known as "mottled enamel." Recent investigations have shown that this

pathological condition, which occurs in many districts of the United States, is induced by the presence of fluorine in the drinking water. The water of the artesian well which supplies Chetopa was found to contain over 9 parts per million of fluorine, an amount which invariably leads to damaging and disfiguring lesions of the dental enamel.

For several years Dr. J. Scott Walker, a practicing dentist in that city, called public attention to the dangers of the situation with the result that it was proposed to bond the city to the amount of \$25,000 for a new water supply which would be free from fluorine. Last August this proposal was voted on but defeated, which meant that the dental defects would continue to develop in succeeding generations. Dr. Walker has continued his agitation and has brought it about that the monthly water bills bear the legend: "This water is unfit for consumption by children." It is clear that the matter is by no means settled.

This incident is of interest to public health authorities, not only because the officials of this community decided to save money rather than to eradicate a menace to the health of the community, but even more so because it illustrates what can be done by an energetic and persistent individual in the face of a lack of coöperation. The ingenious method of calling direct attention of the residents to the limitation in potability of the water might be of service to others who are concerned with similar problems.

BERNHARD BANG

FROM Europe comes the notice of the death of Bernhard Bang, one of the leading veterinarians of his time, in his 85th year.

The announcement of the discovery of the tubercle bacillus by Koch came 2 years after his graduation in veterinary medicine. He was one of the early converts to the science of bacteriology and carried out researches on many of the infectious diseases of domestic animals, two of which at least are known to be communicable to man—tuberculosis and bovine abortion. He devoted a great deal of time to the study of the eradication of bovine tuberculosis from cattle, and in 1894 put forth the method known by his name for converting a diseased herd into a healthy one, based on the knowledge that tuberculosis is not an inherited disease. His plan was to separate the newborn calf from the diseased mother within 48 hours of birth, and rear it on milk from a healthy nurse mother, or else on pasteurized milk.

When the diseased cattle had open tuberculosis and were dangerous spreaders of the germ, they were slaughtered. The method required a clean barn free from infection in which the new-born calves were reared, and kept when grown, the diseased cattle being housed in a separate building and gradually sold or killed. The method was successful, but has not been largely adopted in the United States on account of the expense. Bang and Nocard were the first two to inoculate cattle with emulsions of the tubercle bacillus intravenously, the animals being slaughtered within an hour and the tissues examined for the germ of tuberculosis. Their experiments were negative. The object was to determine whether or not the eating of meat from tuberculous animals was dangerous to man.

The second discovery of Bang was that of the germ of contagious abortion, described in 1897. He did not recognize it as being related to the bacillus of Malta fever, isolated by Bruce some 10 years before, but, in 1918, Alice Evans, of the Hygienic Laboratory of the U. S. Public Health Service, now the National Institute of Health, showed the close relationship between the two organisms. Since that time it has been found that the disease is quite widely spread. A number of outbreaks in cattle have occurred, and a considerable number of cases of undulant fever due to the organism have been observed in man.

Bang was born in Zealand, educated there and at Copenhagen. He was appointed Professor of Internal Diseases in the Royal Veterinary College in Copenhagen in 1892, and retained the chair until 1914. We owe much to veterinary science in the development of bacteriology and the study of disease of animals transmissible to man, and to Bernhard Bang, our debt is especially heavy.

ASSOCIATION NEWS

WILLIAM HALLOCK PARK, M.D.

WILLIAM Hallock Park has been awarded the Sedgwick Memorial Medal for distinguished service in public health. The choice was unanimous and enthusiastic, and the announcement at the Washington Annual Meeting was greeted with hearty and spontaneous applause. Dr. Park's work and accomplishments had placed

his name in the hall of fame long before this recognition of his achievements. It is given to few men to serve so long and so well. For 39 years Dr. Park has been Director of the Bureau of Laboratories of the Department of Health of the City of New York. He was a pioneer in bacteriology and was of the vanguard in the march of

progress in the practical applications of immunology.

There is not a single disease on our list of communicable infections to which Dr. Park has not made notable contributions, especially in the matter of laboratory aids to diagnosis, and where biologic preparations helpful in prevention or cure were concerned. His contributions to the scientific side of hygiene and sanitation have constituted him an authority and given him world-wide recognition. His profound knowledge of the subject, his rich background of experience, his critical insight, and unusual fund of common sense have made him a guide as well as an authority in sound public health practice. Dr. Park is an able teacher,

a prolific author, a stimulating investigator, and an inspiring leader. He has dedicated his life to work for the betterment of mankind. His kindly disposition, great patience, and fine qualities have made him a man among men. He is loved by his many friends. In honoring him the American Public Health Association honors itself. Dr. Park, enshrined in the hearts of his colleagues, takes an abiding place as a fixed star of first magnitude in the galaxy of preventive medicine.

He has been a member of the A.P.H.A. since 1912, and is a Charter Fellow, elected in 1923.

M. J. ROSENAU, *Chairman*
Sedgwick Memorial Medal Committee

LONG AND CONTINUOUS SERVICE

THE JOURNAL gladly notes the long period of continuous health service of Dr. G. D. Lummis, Health Officer of Middletown, Ohio. Dr. Lummis was appointed part-time health officer of this city in May, 1890, and has served continuously as health officer since that time. In 1927 when the population of the city reached 30,000, the position of health officer was placed on a full-time basis.

Dr. Lummis's experience has been utilized also in state and national health organizations. As an early member of the Committee on Administrative Practice of the American Public Health Association, he participated in the first conferences arranged to prepare the appraisal form for city health work. In 1917, Dr. Lummis was appointed to the Ohio State Health Council and still serves.

In commenting upon his administrative health experience, Dr. Lummis states that he has never attempted a

new departure without the advice and approval of the local medical profession. He believes that "no efficient piece of public health work can be accomplished without the coöperation of the medical profession." He also believes that no health department can carry on successfully without a sufficient number of good public health nurses, and he prefers the generalized plan of organization, which is carried out in Middletown.

Under the Health Officer's direction, Middletown has for 11 years maintained a Fresh Air Camp, financed by a private organization. Here 80 children of ages 8 to 12 are cared for each summer for a period of 10 weeks. The camp is of modern construction and has permanent buildings, a sewage disposal plant, city water supply, and all the facilities of a complete camp. During the past summer the average gain in weight per child was 5.8 pounds.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

- R. Dow Collins, M.D., Whitesburg, Ky.,
Director, Letcher County Health Department
- Frederick T. Fitch, M.D., 43 Main St., East Hampton, Conn., Health Officer
- J. Norman Henry, M.D., 1906 Spruce St., Philadelphia, Pa., Director, Dept. of Public Health
- Clarence R. Hepler, M.D., Court House, Wichita, Kans., County Health Officer
- Clarence S. Morse, Board of Health, Amesbury, Mass., Agent, Board of Health

Laboratory Section

- Elfreda L. Caldwell, S.B., Andalusia, Ala.,
Director, Field Research Laboratory, State Department of Health
- Ruth T. Humiston, A.B., Hurlock, Md., Assistant Bacteriologist, State Department of Health
- Charles A. Stuart, Ph.D., Brown University, Providence, R. I., Professor of Bacteriology

Public Health Engineering Section

- Frank S. Tainter, 142 Maiden Lane, New York, N. Y., Engineer, New Jersey State Department of Health

Industrial Hygiene Section

- Michael A. Eiben, 4587 S. Hills Drive, Cleveland, O., Dust Collecting Engineer, Northern Blower Co.
- Harold H. Keller, 1835 Arch St., Philadelphia, Pa., Medical Department Manager, Bell Telephone Company of Pa.

Child Hygiene Section

- Harrison W. Ferguson, D.D.S., 347 Fifth Ave., New York, N. Y., Author and Lecturer (Assoc.)
- Elba L. Morse, R.N., Marquette, Mich., Supt., Northern Michigan Children's Clinic
- Laura B. Wilson, R.N., 125 De Soto St., Pittsburgh, Pa., Supt. and Director of Nursing, Children's Hospital of Pittsburgh

Public Health Education Section

- Mary Bottje, A.B., 190 Jordan Hall, Ann Arbor, Mich. (Assoc.)
- Eunice E. Fetterly, A.B., 711 Arch St., Ann Arbor, Mich., formerly Instructor in

Hygiene, North Carolina College for Women

- Marie P. Hart, M.A., 15 Greenwood Ave., Bethel, Conn., Public Health Nurse
- Dorothy M. Henderson, M.D., Van Hornesville, N. Y., Medical School Supervisor
- Anna L. Ketch, R.N., 10 Park Place, Morristown, N. J., Director, Morris County Tuberculosis Assn.
- Cornelia McKinney, M.A., 1527 Avenue J, Huntsville, Tex., Teacher, Biology Dept., Sam Houston State Teachers College
- Francina McMahan, 88 9th St., Glendale, W. Va., County Health Nurse
- M. Nadkarni, M.B.B.S., Ann Arbor, Mich., Student (Assoc.)
- Joseph E. Ransdell, LL.D., 1381 National Press Bldg., Washington, D. C., Executive Director, Conference Board, National Institute of Health
- Mrs. Inez G. Richardson, 5122 Interior Bldg., Washington, D. C., Administrative Assistant, White House Conference on Child Health and Protection

Public Health Nursing Section

- Helen Bean, R.N., 2 Park Lane, Mt. Vernon, N. Y., Nursing Field Representative, Amer. Red Cross
- Margaret A. Bulkley, R.N., City Hall, 241 W. South St., Kalamazoo, Mich., Supervisor of Nurses
- Margaret L. East, R.N., State Board of Health, 532 W. Main, Louisville, Ky., Director, Bureau of Public Health Nursing
- Kathleen M. Leahy, A.B., 901 W. Franklin St., Richmond, Va., Professor of Public Health Nursing, College of William and Mary
- Mary I. Mastin, R.N., 722 State Office Bldg., Richmond, Va., Director, Bureau of Public Health Nursing
- Gertrude Osborne, R.N., 31 Church St., New London, Conn., Supervisor, Visiting Nurse Assn.

Epidemiology Section

- Filip C. Forsbeck, M.D., Lansing, Mich., Epidemiologist, State Dept. of Health
- NeoKarl Yang, M.D., Dept. of Health, Shanghai, China (Student at Johns Hopkins—Assoc.)

LETTER TO THE EDITOR

TO THE EDITOR:

CLEANLINESS Institute has been added to the list of organizations which have become victims of the prolonged economic depression. On December 14, at the 1932 Annual Meeting of the founders and supporters, the Association of American Soap and Glycerine Producers, Inc., it became evident that no new money for a third 3-year agreement, not even for a 1-year-1933 budget, was available from the member companies. So, on the basis of a decision by the Board of Directors, plans were immediately made to discontinue Institute professional activities and disband the staff.

On December 15, all full-time members of the Institute staff and office force—48 in number—were assembled by the general manager of the Soap Association, who regretfully gave all present notice of dismissal. It is expected that the exodus of staff will be completed January 15, 1933, by which time the health, school, industrial, and editorial services will have wound up their respective work.

From the beginning, the Board of Directors of Cleanliness Institute gave its professional staff freedom of action in dealing with cleanliness in relation to other subjects. As a staff, we saw very little of these, our generous supporters, for their meetings were infrequent and

brief. We believed in our work and are deeply sorry that economic circumstances make continuance without interruption impossible.

During the life cycle of 6 years the professional staff of the Institute received from health and education leaders all over the country many evidences of friendliness, encouragement, appreciation, and interest in this large scope experiment in cleanliness. We are already somewhat scattered, but if my associates knew I was taking this means of thanking the thousands of health officers, public health nurses, and others, with whom I, myself, have been in touch during this period, I am sure they would join me in this expression of gratitude.

At the same time, in this public way, I would like to pay tribute to my former associates in Cleanliness Institute. Most of their names are already familiar to many of the readers of this JOURNAL. They include in the Health and School Service, Julia B. Tappan, Mary P. Landrine, C. Margaret Munson, Evelyn R. Noé, Lillian Peltz, and Anne Raymond; in Editorial Service, Florence M. Seder, Helen B. Ames, Diana Erler, and Josephine Nelson; in Industrial Service, Nelson N. Marshman; in Administration, Roscoe C. Edlund.

W. W. PETER, M.D., DR.P.H.

PUBLIC HEALTH ADMINISTRATION

Anderson County (S. C.) Health Unit—Within 30 days following the completion of its fiscal year on October 1, the Health Unit has distributed an annual report which pictures the progress of health work in this area during the past 10 years with particular reference to the reduction in the prevalence of smallpox, typhoid fever, diphtheria, and pellagra.

This County Health Department boasts of a personnel of 3 individuals: 1 physician, 1 public health nurse and 1 stenographer. In 1932 the amount appropriated was \$6,000, only 7 cents per capita.

The number of reported cases of smallpox has steadily decreased with the increase in the number of vaccinations. Last year no case of smallpox was reported. During the 10-year life of the Health Unit 20,664 smallpox vaccinations have been performed. There have also been 78,220 typhoid inoculations with a steady decrease in the morbidity rate. With the protection of 4,289 children the diphtheria death rate has been reduced by 50 per cent. Sanitation, malaria control work, supervision of dairy farms, and maternity and infancy hygiene have received particular emphasis.—Anderson County Health Unit, S. C., 1932.

Rockefeller Foundation—During 1931 the Foundation has extended its coöperative services for the control of disease, not only by supporting research and epidemiological studies but more especially has directed its effort toward extending knowledge concerning the cause of illness. In this work assistance has been granted to 47 countries throughout the world and the health

departments of 37 states have been aided. Assistance has not been limited to central health services but has also been granted to local authorities.

To the Health Organization of the League of Nations contributions have been made to assist in the international interchange of public health personnel and to maintain a world-wide system of health statistics. Among the special activities may be mentioned those in connection with tuberculosis, respiratory diseases, undulant fever, and special studies of sanitation and administrative service. Noteworthy in the field of research is the work on hookworm, malaria, and yellow fever.—The Rockefeller Foundation, *Annual Report*, 1931.

Medical Participation in School Health Service—Recently, the Detroit Department of Health has been compelled to exercise several economies in its program due to the inability of the city to provide all of the funds appropriated for the current fiscal year. The two services which have been eliminated are the School Dental Service and the group of part-time physicians who performed the physical examinations for school children. The dental service has been reëstablished in two ways: In the first place the Children's Fund of Michigan has appropriated \$25,000 with which to maintain an emergency dental service in the school clinics, and, second, the District Dental Society, through a group of volunteer dentists, has provided a dental examination for school children and is manning the central clinic of the Department of Health.

Through the coöperation of the

Wayne County Medical Society, there are approximately 100 physicians who are giving 2 hours every other week for physical examinations for children in the public and parochial schools. Of special note is the fact that the Board of Education has officially designated the Medical Society as an agency to coöperate with the Health Department in providing such examination. The Director of the School Health Service of the Health Department is Secretary of a sub-committee of the County Medical Society which directs the service.

As a means of carrying on during the emergency created by the depression, this plan has proved highly satisfactory and has stimulated a further interest on the part of the physician in the program of medical participation in health work. Through this coöperative plan more and more physicians are becoming impressed with the need of health service for school children and are assuming greater interest in the plan for periodic health examination to be conducted among their own clientele.

A Revenge Epidemic—The Greenville, S. C., health officer recently recorded an epidemic of vomiting, involving hundreds of cases reported by physicians, each case being attributed to the ingestion of sandwiches containing mayonnaise from a single shop. Symptoms included nausea, vomiting from 20 minutes to 3 hours after eating, abdominal cramps or dull aches of varying duration, with occasional cases of diarrhea. The patients were ill for 1 or 2 days.

Epidemiological studies and inspections, coupled with laboratory tests, revealed an interesting course of events. Until 2 weeks prior to the trouble, Mrs. A and Mrs. B had conducted a sandwich shop in partnership. Disagreement terminated the partnership and caused Mrs. B to open a shop in competition next door to Mrs. A. Evidence

was secured that Mrs. A had been seen in Mrs. B's plant without permission or knowledge of the owner. Among several cans of cottonseed oil in good condition was found one can which contained fish oil. It was also established that the contents of this can had been used for the manufacture of mayonnaise used in the sandwiches in question, the strong odor not having been detected by the workers until after the epidemic.

Laboratory examination of the mayonnaise and oil revealed a glucose-fermenting motile bacillus which was identified as *Bacillus enteritidis*. It was concluded that Mrs. A desired revenge, substituted fish oil for cottonseed oil, hoping to create a bad taste in Mrs. B's mayonnaise. The fish oil was made from fish heads and tails, by-products of the fishing industry, providing a habitat for organisms of the enteritidis family.—Irving S. Barksdale, M.D., *South. Med. & Surg.*, Charlotte, 94, 10 (Oct.), 1932.

A Recreation and Health Project—The Bellevue-Yorkville Health Demonstration Center has coöperated since 1927 with local agencies, including the National Safety Council, in the development of a recreation program for the district where fatal accidents were high, especially among children under 15 years. Increased recreation facilities were developed, and grade school buildings were opened as vacation playgrounds. The yard playground, utilizing space in sections where large grounds are too costly, has proved of value but difficult to administer. Day outings for children, when conducted regularly and scheduled for places not too crowded, proved beneficial.

Auxiliary play services in clinics demonstrated the possibility of making children's waiting rooms attractive to the child. Volunteer service in supervising the use of toys and talking with

mothers regarding children's play habits became a useful supplement to health education given to mothers and children by the clinic nurse. A safety patrol plan proved successful in the majority of playgrounds. Educational material consisting of display posters, pamphlets, and project suggestions were helpful to playground directors.—Thelma E. Carpenter and Savel Zimand, *Recreation Program of the Bellevue-Yorkville Health Demonstration*, 1927–1930, New York, 1932.

Bridgeport, Conn.—In the 1931 report of the city health department

(population 147,101), attention is directed to a decrease in diphtheria from 254 cases and 18 deaths in 1925 to 32 cases and 1 death in 1931. In 1925 there were 143 cases of diphtheria admitted to hospital as contrasted with 26 in 1931. In 1922, hospital days (3,095) for diphtheria amounted to 23 per cent of the total days for all admissions (average 17 days each), while in 1931, only 1.4 per cent of the communicable disease hospital days were for diphtheria (313 days, average 12 days). Last year, 182 scarlet fever cases averaged 26 days in hospital.—*Bridgeport Municipal Register*, 1931.

LABORATORY

REPORT OF THE REFEREE ON OYSTER ANALYSIS*

THE last report of the Committee on Standard Methods for the Bacteriological Examination of Shellfish was presented and adopted in 1920, and was printed in *The American Journal of Public Health*, Vol. xii, p. 574 for July, 1922.

Since that time the method recommended has been in general use in all parts of the country. The very fact, that in the past 10 years there has been no general criticism or demand for change, indicates that on the whole the method has proved eminently satisfactory.

Of course many studies have been reported of other methods of examination than those recommended in Standard Methods. None of these however, has been as simple for general routine work, and none of them seems to give a more accurate determination of the actual sanitary condition of the oysters.

The two main questions that have been raised by these investigators are, first, the method of securing samples of the shell liquor, whether by the ordinary process of opening with a knife thrust in between the shells, or by drilling through the shell; and second, whether the analysis of the shell liquor gives a true measure of the presence of the coli-aerogenes group in the oyster.

On the first point it may be said that in most laboratories where oysters are examined, the workers find little difficulty in draining the shell liquor from the oyster by prying the shells slightly open with a regular oyster knife. The method is rapid, the liquor is not easily contaminated, and it requires a minimum of apparatus and sterilized equipment. Where many specimens are to be analyzed in a day the saving of time is important.

On the second point numerous investigations have shown that practically nothing is gained by attempting to get at the stomach and intestinal contents in addition to the shell liquor. If mem-

* Presented to the Committee on Standard Methods of the Laboratory Section of the American Public Health Association, at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

bers of the coli-aerogenes group are present anywhere in the oyster they will always be found in the shell liquor.

It is important, however, to prevent as far as possible the dilution of the shell liquor with the sterile blood of the oyster. If the shell liquor only is drained from the shell and the knife is not allowed to cut into the body, in an effort to cause a greater flow of fluid, this will be avoided. We have suggested below a slight change in the wording of Standard Methods to call attention to this.

In view of the fact that a considerable number of laboratories are now engaged in the analysis of other shellfish than oysters, such as clams, quahaugs, mussels, etc., and that methods applicable to oysters are not always suited to these other shellfish, it is recommended, first that the title of this particular part of Standard Methods be changed from "Standard Methods for the Bacteriological Examination of Shellfish" to "Standard Methods for the Examination of Oysters," and second that a sub-committee be appointed to draw up methods for the examination of these other shellfish.

Below you will find in detail the changes that I suggest in the present Standard Methods:

Change in title—Standard Methods for the Bacteriological Examination of Oysters.

OYSTERS IN THE SHELL

Collection of Sample—no change.

Transportation of Sample—no change.

Condition of Sample—substitute for the whole paragraph the following: "All oysters used for the analysis shall be in apparently good condition. No oyster from which the

shell liquor has escaped, or whose shell is not tightly closed at all times while under observation shall be used for the analysis."

Technical procedure—line 9. Substitute the following for the rest of this section beginning "The oysters shall be opened," etc.—"With an oyster knife that has been sterilized by flaming, the shells of five oysters shall be pried open sufficiently so that all the shell liquor is drained aseptically into a sterile wide mouth bottle. Care shall be taken not to puncture the body of the oyster, in order to prevent the dilution of the shell liquor with the sterile body fluids. The composite shell liquor of the five oysters shall be shaken thoroughly and from it shall be prepared dilutions of 1 to 10, and 1 to 100, using sterile sea water or distilled water containing 2 per cent sodium chloride.

Five 1 c.c. portions of the undiluted composite shell liquor, five 1 c.c. portions of the 1 to 10 dilution and five 1 c.c. portions of the 1 to 100 dilution shall be added to fermentation tubes containing standard lactose broth.

The further procedure for the determination of the presence of members of the coli-aerogenes group shall be exactly as specified in *Standard Methods of Water Analysis*, and shall include the presumptive, partially confirmed, and completed tests as required.

Bacterial Counts—no change.

OYSTERS REMOVED FROM THE SHELL (OPEN OR SHUCKED STOCK)

Omit the last paragraph as published in the *American Journal of Public Health*, July, 1922. This paragraph does not appear in the reprints, also substitute "coli-aerogenes group" for "B. coli" in the third from the last line.

EXPRESSION OF RESULTS

Paragraphs 1, 3, and in the tables, substitute "coli-aerogenes group" for "B. coli."

Brown University,
Providence, R. I.

APPARATUS FOR STUDY OF THE BACTERIAL BEHAVIOR OF AIR

W. F. WELLS

Harvard School of Public Health, Boston, Mass.

QUANTITATIVE examination of water for non-pathogenic bacteria has become a vital factor in the design, operation, and control of water supply systems, and the sanitary control of streams, bathing places, and shellfish grounds. If air bacteriology in a similar way is to determine in the future the hygienic characteristics of air supply and conditioning systems, it becomes necessary, because of the wide variability of bacterial results, to accumulate more extensive data than are at present available. This necessitates the development of a convenient method by which observers will obtain comparable results.

The author has developed a simple instrument for this purpose, utilizing the principles of the centrifuge in the separation of bacteria and other fine particles from gaseous suspensions such as air. This device operates somewhat in the manner of a milk clarifier which separates heavier particles from a liquid medium. The rapid revolution of a glass cylinder about its vertical axis causes a current of air to enter through a central axial tube, and to escape along a thin layer of nutrient medium supported on the walls of the cylinder. Particles suspended in the air are deposited on the medium. Colonies develop where the individual bacteria have been precipitated and can be counted with the naked eye.

Four independent operations are combined in one compact instrument:

1. Air flow is created.
2. The amount of air is measured.
3. The bacteria are collected.
4. The bacteria grow and can be counted on the collecting medium without separate plating.

The instrument has been subjected to approximately 200 tests, serving three general types of purposes. These are.

to determine the characteristics of (1) atmospheric reservoirs, (2) conditioning equipment, and (3) bacterial sources of aerial contamination.

1. In the study of atmospheric reservoirs, a representative series of tests has been carried on at the laboratory during the past 6 months to determine the effect in one locality of seasonal, diurnal, and meteorological influences.

2. In the study of conditioning equipment, a most interesting observation has been the discovery that certain air blowers remove over 90 per cent of bacteria from air, while others

do not appreciably affect the bacterial content. With the increasing use of fans and centrifugal blowers, this fact may prove of practical importance.

3. In the study of the bacterial sources of aerial contamination, experiments have been made to determine

under what conditions bacteria are given off by persons confined in a limited space. This inquiry leads also to an investigation of the physical, chemical and biological properties of droplets in connection with the theory of droplet infection.

VITAL STATISTICS

Increased Tuberculosis Mortality in Young Women in England— A noteworthy feature of the latest London mortality statistics is the lack of decline in recent years in mortality from pulmonary tuberculosis among young women.

In his annual report for 1927 the Registrar-General of England and Wales pointed out that women of 15 to 35 years of age formed the only section of the population in which an improvement in mortality from phthisis had not been observed in recent years. The cause of this phenomenon has not so far been adequately explained, though it has commonly been attributed to the increase of young women in industrial and commercial employment.

In London, according to the mortality rates set out in this report, the phthisis mortality among women has actually risen, between 1911-1913 and 1929-1931, by 23 per cent at ages 15 to 20, and 30 per cent at ages 20 to 25. In every other age group, and at every age among males, a decline is registered. When these deaths from pulmonary tuberculosis, at ages 15 to 25, are stated as a percentage of the deaths from all causes at the same ages, it is found that London shows the greatest relative increase in phthisis, the rural districts of the whole country showing almost no change between 1911-1913 and 1928-1930. The suggestion is that in the rural areas the occupation of young women has not changed to the

same extent as in urbanized areas. Yet when the London figures are considered in more detail by the comparison of two groups of boroughs—those representing the poorest population and those representing better-class areas—it is found that the increase in the percentage of pulmonary tuberculosis as compared with all deaths among young women of 15 to 25 is much the same in both groups.

If change of employment from domestic work to commercial or industrial occupations or "industrialization" were alone the cause of the increased mortality from phthisis, the change should be far more conspicuous in the better class areas; for in these, the occupation figures of the census years 1911 and 1921 show that, in the 10 years intervening between them, the proportion of young women of this age engaged in domestic service decreased by nearly one-half, while in the poorer group of the population, the number employed in domestic service is comparatively negligible in both censuses.

An analysis of further available data shows that practically the whole of the increase in mortality from pulmonary tuberculosis in London has been among single women. The obvious explanation that young women suffering from phthisis do not marry is insufficient to explain the considerable divergence in mortality between the single and the married women. The possibility cannot be excluded that it is the young unmarried women who are likely to be most adversely affected by economic conditions. As (judging by mortality

rates) their resistance to pulmonary tuberculosis in the early years of adolescence is less than that of young men, it is only to be expected that when adverse economic conditions are added at this period of life, the young women will be much more affected than young men. If this is the explanation of the facts, an improvement in economic conditions affecting young women wage earners should be followed by a decline in this excessive mortality.

A factor which has not been considered in this report, but which may affect London to a peculiar degree, is internal migration. It has been shown that in all probability the relatively low phthisis rates in the urban areas and the relatively high rates in the rural areas among young adults—especially women—are related to the migration of the more physically fit from the country to the town, the town mortality being lowered, and the country mortality increased, by this movement of the healthiest. If, as there is some reason to believe, this selective migration to London has been slackening of recent years, the London mortality rates, especially from phthisis, are likely to be swollen owing to this relative absence of healthier recruits. Though this might be a practical explanation of the abnormal rise shown in the London rates, it obviously fails to be a complete explanation, since, as has been pointed out, the lack of decline in pulmonary tuberculosis in young females extends to the whole country.—*Lancet*, 16:866 (Oct. 15), 1932.

Aviation Mortality in 1931—The fourth report of the committee, on aviation of the Actuarial Society of America indicates that improvement has taken place in some aspects of the mortality experience due to flying. A summary of the findings made known by J. E. Hoskins, assistant actuary of the Travelers Life Insurance Company

and chairman of the committee reveals that, in 1931, there was an improvement in mortality in civilian flying other than schedule flying, but no significant change in experience under schedule flying or in military flying.

The passenger death rate in schedule flying is given as 2 deaths per 100,000 passenger hours, or 5 per 100,000 flights. On the basis of the number of passengers carried on schedules and the number of deaths occurring in this type of flying, the experience in 1931 was 1 fatality for every 19,346 passengers carried. In 1930, the death rate was 1 fatality for every 17,396 passengers, while in 1929 it was 1 for every 9,633 passengers, and in 1928, 1 fatality for every 3,314. Stated on the basis of the number of flights, the death rate of passengers was 30 per 100,000 flights in 1928, 10 in 1929, 6 in 1930, and 5 in 1931.

In short sightseeing flights, the mortality rate, per 100,000 passengers, was about 3, and the rate per 100,000 passenger hours about 9. The death rate of passengers in pleasure flying was about 25 or 30 per 100,000 flights. In pleasure flying the death rate per flight seems very high, although it shows some improvement. In that connection it was mentioned in the report that much of the flying is done by inexperienced or unlicensed pilots.

A distribution of passenger fatalities by kind of flying in 1931 revealed 27 deaths under schedule flying for hire and 105 in pleasure flying. Passenger fatalities for the year totalled 183. The mortality rate of commercial pilots ranged between 20 and 25 per 1,000. Indications pointed to a lower rate for amateur pilots. The report states that a very small amount of annual flying by amateur pilots leads to a low rate of mortality per year, although perhaps a high rate of mortality per hour. The mortality among students was said to be relatively low, but the report adds that

after a license is obtained, and particularly after the student qualifies for a transport license, the mortality rate increases sharply for a time, then decreases gradually, but seems to level off with no appreciable improvement after about 1,000 hours in the air. It is indicated that the mortality rate of regular army and naval pilots is higher on an hourly basis than that of scheduled commercial pilots but lower than that of non-scheduled commercial pilots in general.

The mortality experience of licensed pilots shows that in 1929 there were 34 deaths for each 1,000 transport pilots, as against 23 per 1,000 in 1930, and 19 in 1931. It was thought that the improvement might have been due to a temporarily decreased amount of flying. The death rate among limited commercial pilots was 18 per 1,000 in 1929, 20 in 1930, and 9 in 1931. Among private pilots the death rate in 1929 was 12 per 1,000, as against 14 in 1930, and 8 for 1931.

The more experienced class of pilots has consistently exhibited the highest rate of mortality per year, while the less experienced class has in general exhibited the lowest rate. This is explained by the fact that the mortality rate increases with the amount of annual flying time, although not in direct proportion. Among transport pilots the mortality is said to be high for those with less than 500 hours' experience, while the available evidence indicates no material improvement in the annual mortality rate after 1,000 hours' experience has been passed. A relatively high mortality was said to exist among pilots of 2,000 or more hours' experience.

The report indicates that in 1930 there was a passenger death for every 4,300,000 passenger miles flown, as against 1 death for every 440,000,000 railroad passenger miles. In 1931 there was a passenger fatality for every

4,600,000 passenger miles flown.—*Insurance Field*, 61:5, 17 (Oct. 14), 1932.

A Comparative Study of Acute Anterior Poliomyelitis in Philadelphia in 1916 and 1932—This year has witnessed the second extensive outbreak of epidemic poliomyelitis in Philadelphia, the first being in 1916. In the intervening years no definite outbreaks have occurred, although the years 1930 and 1931, inclusive, exhibited an unusual number of cases. In fact, starting with 1929 there has been a steady yearly increase of cases from 45 in 1929, to 106 in 1931. In the 1916 epidemic there were reported 1,006 cases with 307 deaths, giving a case death rate of 32 per cent. To October 1 this year there have been 645 cases and 73 deaths, with a case death rate of a little over 11 per cent, as compared with a 30 per cent case death rate for the corresponding period of 1916. The fractional death rates, however, are hardly comparable, inasmuch as in 1916 the diagnostic criterion was paralysis, whereas in 1932 many cases in the preparalytic stage have been included.

Not only is the fatality rate lower in this year's epidemic, but the type of the disease is less severe, resulting in relatively less permanent paralysis. In both epidemic years 1 case each was reported in the month of June; 37 and 26 in July; 445 and 318 in August; and 365 and 306 in September of 1916 and 1932, respectively. The peaks in both epidemics were reached in the fourth week of August with 133 and 118 cases, respectively. The greatest number of cases reported in a single day was 36 on August 22, 1916, and 21 cases on August 28, 1932, almost a week later.

The parallelism continues fairly true as to location of first appearance and geographical distribution. Both epidemics seem to have originated during the month of July from a focus in

South Philadelphia, comprising the 1st, 2nd, 26th and 39th wards. In 1916 there was a coexisting focus in North Philadelphia in the 43rd ward, and in 1932 a similar accessory focus in Central Philadelphia in the 15th ward. In 1916 the disease expanded from the aforementioned foci to involve South, North, and Northwest Philadelphia, and North and Southwest Philadelphia. The banner ward in South Philadelphia was the 39th with 63 cases; in North Philadelphia the 43rd ward with 63 cases; in Northwest Philadelphia the 22nd with 79 cases, and in West Philadelphia the 40th with 42 cases. So far this year the same trend of expansion has been followed with the exception of an early simultaneous explosion of cases from the 15th ward instead of from the 43rd ward as in 1916.

The similarity of dissemination along certain ward boundaries that are highly congested may be explained as offering the maximum opportunity for contact infection. This year's wave has been a little later in getting started, it has not approached the 1916 incidence, and from present indications has already spent its force. Inasmuch as both outbreaks reached their peaks about the same time it may be deduced that their declines will relatively parallel, and that return to normalcy may be expected by December of this year. At this time the outbreak is actively receding, there having been but 45 cases reported for the week ending October 1, 1932, and the daily cases since then have been averaging 4 per day.—*Monthly Bull.*, Philadelphia Dept. of Health, Nov., 1932, p. 3-4.

A Tuberculosis Survey of the Territory of Hawaii, 1931—Tuberculosis, causing some 400 deaths every year in Hawaii, and approximately 200 deaths a year in Honolulu, is generally recognized as being one of the gravest of health problems in the Territory.

In 1931, the death rate from this disease, per 100,000 population, was 106 for the Territory and 148 for Honolulu, compared with a rate of 75 in 1929 for the death registration area of the United States.

The average death rate from tuberculosis, by 5-year intervals, shows that there was a decline for the Territory of 9 per cent from 1900 to 1919 and a 31 per cent decline during the next 10 years. For Honolulu, the decline was more uniform. While the tuberculosis death rate has declined 62 per cent in the registration area of the United States during the past 30 years, the decline during the same period in Hawaii has been approximately 40 per cent, while for Honolulu a 78 per cent reduction has been noted.

When the tuberculosis mortality rate for Honolulu is corrected for residence, it is approximately 127 rather than 148 for 1931. It is obvious, however, that even after correction for residence, Honolulu's tuberculosis mortality rate is higher than that for most cities with populations of comparable size.

Hawaii's death rate from tuberculosis (106) is greater than that for any state on the mainland with the exception of Arizona (275.9), New Mexico (158.8*), Colorado (117.5*) and Tennessee (108.7). It should be noted that these four states are either health resort states or southern states. In the latter, a high negro death rate affects the figures.

The greatest number of deaths from tuberculosis occur among people in early adult life, the maximum number of deaths occurring in the age group from 20 to 39 years. It is the leading cause of death among persons from 10 to 50 years of age. Thirty-seven per cent of all deaths from tuberculosis are concentrated in the age group between 15 and 35 years, a group which contains

* 1930 death rate.

38 per cent of the population of the Territory. In the later age groups, although the actual number of deaths is small, the death rate from tuberculosis continues its upward trend to the oldest age groups, due to the relatively smaller number of persons living at those ages. This curve of tuberculosis mortality rate by age in the Territory shows a more marked rise in the older age groups than that for the registration area of the United States.—*A Tuberculosis Survey of the Territory of Hawaii and City and County of Honolulu*, 1931, pp. 15-19.

Hospitalization of Mental Patients
—Results of enumerations of patients in state hospitals for mental disease for 1929 and 1930 were recently announced by the U. S. Bureau of the Census. The total number of patients on the books of the 164 state hospitals and 2 federal hospitals (St. Elizabeths Hospital, Washington, D. C., and Asylum for Insane Indians, Canton, S. D.) at the end of 1930 was 323,688. This number represents 236.1 persons per 100,000 of the general population.

It was said that the hospitals during 1930 cared for a daily average of 31,422

patients above their normal capacity. During 1930 the hospitals admitted 62,738 patients for the first time and 15,714 who had previously been treated in hospitals for mental disease. Men outnumbered women among first admissions, 144.8 to 100. Dementia praecox was the diagnosis in more than 20 per cent of the new admissions, 13,047 cases in 1930 and 12,187 during 1929.

Among readmissions manic-depressive psychosis was the most frequent cause, a situation attributed to the recurrent nature of the disease. There were nearly as many readmissions for this disease as new admissions; the latter amounted to 14 per cent of all new admissions.

In 1930, 38,538 patients were discharged; 29.6 per cent as recovered; 45.6 per cent, improved, and 10.9 per cent, unimproved. There were 26,923 deaths of mental patients in state hospitals in 1930, a mortality rate of 89.7 per 1,000 patients under treatment. The cost of operation for 160 hospitals in 1930 was \$105,733,982, a per capita cost of \$302.64. The personnel included 45,817 officers and employees.—*J.A.M.A.* 99:1363 (Oct. 15), 1932.

PUBLIC HEALTH ENGINEERING

PUBLIC HEALTH ENGINEERING MANUAL*

THE Committee on Public Health Engineering Manual was appointed to collaborate with similar committees of other sections in the activities of the Sub-committee on Manual of Administration of the Association's Committee on Administrative Practice. Lack of funds with which to function apparently

has temporarily checked activities of Manual of Administration Sub-committee and for this reason your chairman has not formally organized the section committee and made arrangements for work assignments. He has, however, conferred with several members of the section with reference to the advisability of preparing a public health engineering manual to serve as a guide to administrative public health officials,

* Report of the Committee, presented to the Public Health Engineering Section at the Sixty-first Annual Meeting at Washington, D. C., October 25, 1932.

particularly in organizing public health engineering divisions, establishing sound policies of operation and proper allocation of funds for engineering activities. He has found enthusiastic endorsement of the project in every case.

It is believed that the section could best serve the public health engineers by preparing a complete manual entirely separate from the public health manual contemplated by the Committee on Administrative Practice. As our section contribution to a general manual, a digest of the public health engineering manual could be prepared; the one committee representing the section in both functions.

The preparation of a public health engineering manual is a sizeable undertaking and it might require from 3 to 5 years for completion. In order to be the most help to the Manual of Administration Sub-committee, it is believed that the first year's effort should deal with the administrative policies, organization, and budget requirements of an engineering division in each of the principal units of public health administration; the federal, state, county, and municipal departments of health. Material of this nature is what is most needed for a public health manual and at the same time it would serve engineers in obtaining proper recognition of their work and policies and in support of their budget requirements.

In later years special monographs on such individual public health activities as supervision and control of water supplies, sewage disposal, swimming

pools, dairy sanitation, insect and rodent eradication, garbage and refuse disposal, environmental sanitation, smoke and other air pollution, industrial sanitation, heating and ventilation, plumbing, housing, noise control, lighting, city planning, disaster relief, and waterways pollution, could be prepared in collaboration with other section committees, the completed work to make up a public health engineering manual of real value to all engaged in public health work and more particularly to the engineers.

Ways and means of financing a complete manual are not yet apparent. It is believed that this is a matter to be left for later consideration when the material is ready. Difficulty is not anticipated in getting mimeographed copies made of the work recommended for next year's activities in collaboration with the Sub-committee on Manual of Administration. Special consideration should be made in appointing the Public Health Engineering Manual Committee of the section to see that its membership includes those engaged in federal, state, county, and municipal public health engineering work. Therefore, it is recommended that the committee be continued with instructions to proceed with the preparation of a manual as suggested above.

SEWAGE DISPOSAL *

THE Committee on Sewage Disposal regrets that it is unable to present

* Progress report of the Committee on Sewage Disposal, presented to the Public Health Engineering Section at the Sixty-first Annual Meeting at Washington, D. C., October 27, 1932.

a report at this meeting of the American Public Health Association. The subject chosen was "The Uses of Chlorine in Sewage Disposal." A large amount of preliminary work has been

done, including the preparation of a very comprehensive bibliography and its arrangement by subjects, together with a study of the historical development. Owing to the demands on the time of various members of the committee, it has proved impossible to cover the ground and formulate a report at this time. The committee, therefore, requests that it be extended for another year, so that the material gathered can be properly studied and compiled, with a view to presenting a finished report

at the meeting of the Public Health Engineering Section in 1933.

FELLOWSHIP AND MEMBERSHIP *

THE Committee on Fellowship and Membership, the purpose of which is to add to the Section membership from among the eligible engineers who are not affiliated with the American Public Health Association, was set up on a geographical basis as given below:

| | |
|----------------|--|
| M. M. Cohn | New York, New Jersey, Pennsylvania |
| G. H. Ferguson | Canada |
| P. G. Galan | Mexico and Central America |
| A. E. Gorman | Michigan, Wisconsin, Min- nesota, Illinois |
| C. E. Green | Oregon, Washington, Idaho, Montana, Wyoming |
| A. P. Miller | Delaware, Maryland, Vir- ginia, West Virginia, North Carolina, South Carolina, Georgia, Florida |
| C. L. Pool | Connecticut, Rhode Island, Massachusetts, Vermont, New Hampshire, Maine |
| L. B. Reynolds | California, Nevada, Utah, Arizona |
| E. W. Steel | Texas, Oklahoma, New Mexico, Colorado |
| E. C. Sullivan | Louisiana, Alabama, Missis- sippi, Arkansas, Missouri, Tennessee |
| M. W. Tatlock | Ohio, Indiana, Kentucky |
| E. L. Waterman | Iowa, Nebraska, North Dakota, South Dakota, Kansas |

A letter notifying each committee member of his appointment and territorial assignments was mailed on February 24.

The names of the 777 engineering prospects used for promotion purposes were selected from the membership lists of the American Water Works Association, New England Water Works Association, the Chlorine Institute, and other smaller miscellaneous groups.

A letter signed by the chairman was mailed to the entire list of prospects on May 19. This letter offered membership and a subscription to the *American Journal of Public Health* for \$5.00, with the option of obtaining a copy of the \$3.00 *Year Book* of the American Public Health Association for an extra dollar. Several other books of interest to engineers were also included in this offer.

Immediately after the May 19 letter was mailed, a list of prospects in the various territories was sent to each committee member, together with a copy of the letter of invitation. The committee members were urged, with the clerical assistance of the Executive Office of the American Public Health Association, to follow up their prospects. Also, on June 7 a copy of the follow-up letter sent out by L. B.

* Report of the Committee, presented to the Public Health Engineering Section at the Sixty-first Annual Meeting at Washington, D. C., October 25, 1932.

Reynolds was forwarded to each member as a suggested form to use. At this time also the committee members were advised of any responses from prospects in their territories to the first letter of invitation.

It is definitely known that 8 of the committee members sent follow-up letters, 7 of which were prepared in the American Public Health Association office and mailed to the committeemen for signing.

On September 27 a second letter was mailed to 425 of the prospects in the states around Washington, D. C. This letter stressed the sessions of the Section at the Annual Meeting, and indicated that members of the American Public Health Association were entitled to reduced railroad fare to Washington. There was also mailed with this letter a copy of the advertisement used in engineering magazines and the list of papers to be discussed at the meeting.

As a result of these efforts, 21 applications were received up to October 20,

all but a few of which were accompanied by membership dues. In addition, there were responses from 30 other individuals, 20 of whom indicated interest in membership but advised that they could not join at the present time due to the economic situation.

Your committee feels that further efforts with this group next year will bring in more new members, and presents this report with thanks for this opportunity to further the interests of the Public Health Engineering Section.

INDUSTRIAL HYGIENE

Chronic Poisoning by Oxalic Acid: With Report of a Case and Results of a Study Concerning the Volatilization of Oxalic Acid from Aqueous Solution—This is a brief report of a case of chronic poisoning by oxalic acid. The victim, a man aged 53, was employed to clean automobile radiators, using a solution of oxalic acid. The solution was made by adding the crystals directly to the radiator and the concentration was apparently from 10 to 20 per cent. After approximately 1 year's work the man became completely disabled. The symptoms appeared to be nosebleed, headaches, vomiting, pain in the back, loss of weight, cough, generalized weakness, and nervous irritability. Reflexes were

apparently normal; there was no swelling of the muscles and joints, and no tenderness on manipulation.

References to the literature would indicate that the toxic action of oxalic acid is brought about by its combination with calcium and the removal of the calcium from its availability to the body as a whole.—Charles D. Howard, *J. Indust. Hyg.*, XIV, 8:283-290 (Oct.), 1932. L. G.

Asphyxia From an Unexpected Cause—In this contribution a peculiar series of events are described in which deoxygenated air high in carbon dioxide found its way through a river bed to the working chamber of a caisson, leading to the death of 5 men engaged in

the chamber. The air had become deoxygenated by passage through the highly organic river bottom and was found to contain approximately 14 per cent carbon dioxide and 0.12 per cent oxygen.—E. L. Middleton, *J. Indust. Hyg.*, XIV, 8:291-294 (Oct.), 1932.

L. G.

Carbon Monoxide Survey in Liberty Tubes, Pittsburgh—This is a report of a study of concentrations of carbon monoxide in the twin Liberty tubes at Pittsburgh. These tubes are approximately 5,900 ft. long and have a cross-sectional area of 468 sq. ft. each. Ventilation is accomplished by 8 Sirocco-type fans located in a fan house directly over the tunnel near its midpoint.

The carbon monoxide concentration determinations were made by the continuous carbon monoxide recorder developed by the U. S. Bureau of Mines. The study disclosed the fact that during the time of the peak load, brief traffic stops were occasioned by minor accidents and indiscretions of motorists, and that the concentrations of carbon monoxide during these periods often exceeded a desirable maximum.

The study recommends that the minimum speed of traffic should be 25 miles per hour and that pedestrians should be prohibited from using the tunnel during the time of such peak loads. There are ten other recommendations of lesser importance to which the reader is referred.—C. B. Maits, *J. Indust. Hyg.*, XIV, 8:295-300 (Oct.), 1932.

L. G.

Modified Form of the Greenburg-Smith Impinger for Field Use, with a Study of Its Operating Characteristics—A modified form of the Greenburg-Smith Impinger apparatus is described. This instrument employs 75 c.c. of water or other sampling fluid, and is so designed that it operates with

a constant sampling rate of air pressure ranging from 30 to 75 lb. without any regulation.—T. Hatch, H. Warren, and P. Drinker, *J. Indust. Hyg.*, XIV, 8:301-310 (Oct.), 1932.

L. G.

The Quantitative Determination of Fine Soot Inhaled by Man—This is a description of a very simple apparatus consisting of a short bent piece of metal tubing approximately 10 to 12 cm. in length and 1.6 cm. diameter, threaded at one end to which a nut is attached. By means of this nut and a sleeve clamp a piece of filter paper is fastened so as to cover one end of the tube. Air is aspirated through the tube at a rate of approximately that of a breathing man.

After a suitable sampling period the filter is removed and compared with a set of color standards. These standards are prepared by suspending soot in chloroform so that the suspension contains 1 mg. of soot per c.c. of chloroform. By using smaller or larger volumes of the suspension, standards of known density are prepared which then serve as a basis of comparison for unknown samples taken at the workplace being studied.—A. I. Burstein, *J. Indust. Hyg.*, XIV, 9:339-344 (Nov.), 1932.

L. G.

The Problem of the Possible Health Hazard of Lead-Weighted Silk Fabric—The increasing use of silk fabrics weighted with lead has suggested this problem to the authors, the purpose of this study being to determine the possibility of lead poisoning from silk weighted with lead salts.

The actual experiments took the form of determining under what conditions body fluids would affect the lead salts in silk fabrics and whether absorption of lead occurs in individuals wearing such material. The experiments were carried out by placing 6" squares of the silk in flasks containing

measured amounts of liquid. The flask was then rotated in an electrically heated water bath for periods of over 3 hours duration at body temperature.

On removal from the bath, measured portions of the suspension were used for analysis. In neutral solutions it was found that the amount of suspended lead was extremely small and that the amount of dissolved lead was either zero or the barest trace, so that micro-chemical methods yielded very minute amounts. Urine, saliva, perspiration, physiological saline, tap water, and distilled water were tested at normal physiological pH's. Only in the case of saliva, tap water and distilled water micro-chemical methods yielded a positive test.

Studies of urine and feces of subjects wearing lead weighted silk garments indicated that no absorption of lead occurs even under extreme conditions, as a result of direct contact of such garments with the skin.—L. T. Fairhall and J. W. Heim, *J. Indust. Hyg.*, XIV, 9:317-327 (Nov.), 1932. L. G.

The Determination of a Single Index of Atmospheric Conditions in Relation to Physiologic Effects—The authors' succinct summary follows:

The physiologic responses of two subjects to moderate effective temperatures were ascertained for 3-hour periods. Tests were made at a wet bulb temperature of from 70° to 85° in moist air (96 per cent saturated) and dry air (40 per cent saturated). The pulse rate observed in the winter experiments agree well with the effective temperature scale, but not that observed in the summer experiments. Owing to acclimatization, the summer pulse was from 2 to 8 beats slower than in winter, the pulse in dry air being only 5 beats greater than in moist air of the same wet bulb temperature, as contrasted with the winter difference of 11 beats.

The rise of body temperature varied in accordance with the effective temperature in winter, but not in summer. The skin temperature of the face varied approximately with the effective temperature, but that of

the trunk showed no sort of correspondence. The loss of moisture by perspiration varied closely with the scale.

One of the subjects performed heavy mechanical work, and his efficiency fell off slightly with rise of temperature. The fatigue experienced varied in accordance with the effective temperature.

It is pointed out that we may be able to obtain a single index to represent the physiologic response of the body to the combined effects of dry bulb temperature, wet bulb temperature, air movement and radiation; but acclimatization must always be taken into account.—

H. M. Vernon, *J. Indust. Hyg.*, XIV, 9:328-338 (Nov.), 1932. L. G.

Studies of School Ventilation—A single monograph includes Contributions Nos. 2 to 6, inclusive, of the reprints of the New York Commission on Ventilation whose work was financed by the Milbank Memorial Fund. All of the articles appeared in the various issues of the *American Journal of Hygiene* between July, 1930, and January, 1932. Their titles follow: (1) A Study of Ventilation and Respiratory Illness in Syracuse Schools; with an Analysis of Factors Affecting Criteria Used; (2) A Study of Ventilation and Respiratory Illness in Syracuse Schools; Rate of Air Flow and Room Temperature in Relation to the Health of School Children; (3) A Study of Ventilation and Respiratory Illness in New York Schools; Comparison of Window-Gravity Ventilation and of Unit Fan Ventilation with Varying Air Flow; (4) A Study of Rural School Ventilation in Cattaraugus County, New York; (5) Vasomotor Reactions to Localized Drafts. E. R. H.

Six Years of Tannic Acid Treatment of Burns—Davison announced his early observations on the tannic acid treatment of burns in 1925. An extensive literature has already appeared on the subject. The present author reports

on 310 consecutive cases at St. Luke's and City Hospitals, Cleveland.

From the work of others it appears that by this method the mortality of burns has been reduced from one-half to one-third, although during the first 24 hours the mortality rate is much the same regardless of the type of treatment used. The tannic acid method prevents subsequent complications to a large extent. In the 310 cases the mortality was 9.6 per cent. In 120 cases treated by various methods prior to 1926, the mortality was 14 per cent.

The exact technic and management of cases is described. Stronger tannic acid solutions (5-10 per cent) are recommended than have been the custom heretofore.—Donald M. Glover, *Surg., Gynec., Obst.*, 54:798-805 (May), 1932.
E. R. H.

Shorter Work Periods in Industry

—Unquestionably the spreading or sharing of work is a most effective emergency measure during a business depression. Whether or not such a policy is necessary or desirable over a longer period is one on which opinions differ.

Statistics show that while improved agencies of production decreased the demand for industrial labor as much as 24 per cent between 1914 and 1925, the demand for manufactured commodities not only re-absorbed these but required an additional $1\frac{1}{2}$ million workers.

Before any permanent change in hours is decided upon the possibilities in the following should be considered: Research, with its potentialities for creating new demands; infant industries that have not yet fulfilled their present demands; the amount of normal business activity necessary to replace old

and obsolete equipment; the rate of pay per hour—if no increase then purchasing power will presumably decline, but if an increase then cost and prices will tend to increase; the fact that substituting a 6-hour for an 8-hour day has, by experience, increased labor demand only from 5 to 25 per cent, and not $33\frac{1}{3}$ per cent as theoretically possible; any redistribution of work and pay roll will mean a sharing of both employment and unemployment, resulting in greatly increased underemployment; the proper use of increased leisure; the reduction in the use of expensive capital equipment; the difficulties attendant upon adopting a policy of shorter work periods almost simultaneously in order to prevent handicap, etc. Experience rather than preconceived opinion is first needed.—National Industrial Conference Board, Nov., 1911. E. R. H.

A Microscopic Study of the Tissues of the Albino Rat Following the Ingestion of Aluminum Salts—The conclusions reached in this study are based upon the findings in 80 test and 22 control animals which had received varying amounts of aluminum salts up to 3.6 per cent of feed by weight.

The protracted ingestion of aluminum salts in concentrations as high as 3.6 per cent has no deleterious effect upon the growth, reproduction, or blood picture of the white rat.

Livers of the animals examined contained a normal amount of iron.

There was no evidence of gross or microscopic pathology in the organs examined which could be attributed to the ingestion of aluminum salts.—Ernest Scott and Mary K. Helz, *Am. J. Hyg.*, 16, 3:865-870 (Nov.), 1932.

E. R. H.

FOOD AND NUTRITION

The Vitamin A, B, C and G Content of Concord Grapes—There has been previously reported work on the vitamin content of Thompson Seedless and Malaga grapes (*A.J.P.H.* 22:548, May, 1932). The Concord grapes tested in this experiment were representative of the fruit available to the consumer. The pulp and juice were fed in 2, 4, and 6 gm. daily amounts for vitamin A, B, and G content, and in 10, 12, and 15 gm. amounts for vitamin C. Eight rats were used for the vitamin A, B and G, and 7 guinea pigs for vitamin C.

It was found that 6 gm. of the edible portion of Concord grapes fed as the sole source of vitamin A induced but little growth in the rats during the 8-week test period. Very small amounts of vitamin B were found. Histological examination of the teeth of the guinea pigs showed no evidence of protection when 10, 12, and 15 gm. of Concord grapes were fed daily. No vitamin G was found.

Malaga and Thompson Seedless grapes were found to be fair sources of vitamin A, B, and C while a small amount of vitamin G was found. These differences may be due to a greater concentration of vitamin in the skins, which were retained in the former experiment and were discarded in the experiment on Concord grapes.—Esther Peterson Daniel and Hazel E. Munsell, *J. Agri. Res.* 45:445 (Oct. 1), 1932.

The Importance of Temperature on the Survival Time of Bacteria in Acid Foods—It is well established that rise in temperature results in increased bactericidal efficiency of the hydrogen ion. Studies were undertaken to determine the effects of low temperature stor-

age of acid foods on the survival of pathogenic bacteria commonly associated with food poisoning. Typhoid strains were also included in these experiments.

The data obtained indicate an appreciable inhibition of the bactericidal effect of the hydrogen ion by such temperatures as -4° C. and -12° C. At such low temperatures organisms of the intestinal group may survive over a period of 7 days. This suggests the possibility of infection by this group of organisms in highly acid foods preserved only by storage at such temperatures. Danger is possibly decreased by the fact that massive infection of the product would be relatively rare. It follows, therefore, that preparation and handling of such foods should be subject to as rigid regulations and inspection as are applied to non-acid types of food.

It is concluded that decrease in temperature allows the survival of organisms of the intestinal group over dangerous periods of time at hydrogen ion concentrations rapidly lethal at ordinary temperatures.—Paul J. Beard and J. P. Cleary, *J. Prev. Med.*, 6:141 (Mar.), 1932.

The Vitamin B and G Content of Raw and Cooked Broccoli—In this experiment, only the edible portion of the plant was used. In determining vitamin B, albino rats, 28 days old, were fed a basal diet consisting of 58 per cent cornstarch, 18 per cent vitamin B-free casein, 10 per cent autoclaved yeast, 8 per cent filtered butterfat, 2 per cent cod liver oil, and 4 per cent Osborne and Mendel salt mixture. After 2 weeks on this diet each animal was then fed daily, 6 times a week, raw broccoli in the amount of 1, 2, 3, and 4 gm. and

equivalent amounts of the cooked vegetable.

Three gm. of the raw material contained 1 unit of vitamin B and induced a total gain in weight of 25 gm. during the test period. Four gm. of cooked broccoli contained no more vitamin B than 2 gm. of the raw material.

In determining vitamin G, the basal diet of Sherman and Spohn (*J. Am. Chem. Soc.* 45:2719, 1923) was modified by incorporating into it alcoholic extract of rice polish. One and two gm. portions of raw and cooked broccoli were fed. Raw broccoli contains a measurable quantity of vitamin G. Rats fed 2 gm. of cooked broccoli gained at a somewhat lesser rate, indicating slight destruction of this vitamin during cooking.—Hazel E. Munsell and Hilda Black Kifer, *J. Home Econ.* 24:823 (Sept.), 1932.

Vitamin C in Canned Citrus Products—In this experiment young guinea pigs weighing approximately 300 gm. were used, the dose being apportioned according to weight. The test was run for 90 days and autopsies performed to determine the Sherman scurvy-score. The oranges and grapefruit were tree-ripened, prepared promptly for canning, heat-exhausted, sealed in plain tin cans, and subjected to a short heat treatment. When the experiments were conducted the citrus products were from 7 to 10 months old.

One gm. per day (6 days a week) of canned orange juice fully protected against scurvy in a 90-day test period. Canned orange slices, canned grapefruit slices and canned grapefruit juice were slightly less effective than canned orange juice, slightly more than 1 gm. daily affording protection against scurvy. Commercially canned orange juice, orange slices, grapefruit juice and

grapefruit slices, after 9 months' storage, contained fully as much vitamin C as fresh citrus fruits.—Carl F. Fellers and Paul D. Isham, *J. Home Econ.* 24:827 (Sept.), 1932.

Rickets in Rats. XIII. The Effect of Various Levels and Ratios of Calcium to Phosphorus in the Diet Upon the Production of Rickets—This is a study of the relative as well as absolute amounts of calcium and phosphorus in the diet in connection with production of rickets. Varying amounts of CaCO_3 and Na_2HPO_4 were given to 24 day old rats. After 21 days on the diet they were X-rayed, killed by bleeding, and blood serum analyzed for calcium and phosphorus.

The bones were examined histologically and the ash content determined. The calcium and phosphorus ratios were 1:1, 2:1, 3:1, 4:1, 6:1, and 8:1. In each ratio there was a variation in the level of both calcium and phosphorus from low to actually high amounts.

The results of this experiment show that for the same ratio a diet becomes less rachitogenic as the total salt level is raised; also that within the range the rickets are more severe the greater the ratio at a given level of phosphorus. The blood serum phosphate decreases with increasing ratio at each level of calcium, and the phosphate of the serum increases with the salt present. For a given level of calcium an increase in the ratio of calcium to phosphorus results in a decrease in bone ash. At a given ratio of calcium to phosphorus, increasing the salt level increases the ash in bones.—Helen Bennett Brown, Alfred T. Shohl, Edna E. Chapman, Catharine S. Rose and Esther M. Saurwein, *J. Biol. Chem.* 98:207 (Oct.), 1932.

CHILD HYGIENE

CHILD LABOR AND CHILD HEALTH

CHILD labor is serious at any time; but during the present crisis it is especially alarming, as it not only tends to disturb further the economic balance, but adds to the hardships and ill health of many children. It is important, therefore, to have clearly before us the picture which child labor presents today. Its newer aspects look upon health protection, vocational education, recreation, accident prevention, workmen's compensation, and proposals for health insurance.

Child labor has been defined recently by the National Child Labor Committee as "the work of children under conditions that interfere with their physical development, education, and opportunities for recreation. It is the employment of children at unfit ages, for unreasonable hours, under unhealthful or hazardous conditions, or while school is in session."

The White House Conference on Child Health and Protection devoted considerable time to the consideration of this subject. The report of the Committee on Vocational Guidance and Child Labor is replete with valuable information and recommendations.

"The task of the Child Labor Section of this Committee has been to set up certain standards for the health and protection of working children. It has reaffirmed the conviction expressed in the earliest child labor legislation that education and freedom from premature toil go hand in hand and must advance together, and it has given evidence to show that labor in immaturity thwarts normal physical development. It has agreed that children under 16 should not be permitted to leave school for

work, and boys and girls of 16 and 17 in industrial employment should not be suffered to enter occupations known to be physically or morally hazardous, to work more than 8 hours a day or 44 hours a week, or to work at night, and minors should be given special protection from hazardous and injurious employments. In the light of present knowledge of the mental and physical needs of the child and the adolescent these standards represent a minimum. They should be looked upon as merely a point of departure for higher goals which the constantly growing contributions of scientific research will reveal."*

The 1930 United States Census states that over 2 million children between 10 and 17 years of age were gainfully employed at that time. The National Child Labor Committee feels that this figure is an understatement of the actual child employment as "it does not include children under 10 years, a considerable number of whom are engaged in street trades, tenement home work, and agriculture. Nor does it include the many thousands of children engaged in beet cultivation and other forms of industrialized agriculture whose work does not begin until after April 1, the date on which the Census was taken."†

The abstract of the report on child labor submitted to the White House Conference states that "children are employed by the hundreds and thousands in a great variety of non-agricultural occupations, chiefly in factories, but also in stores, offices, laundries, res-

* *Child Labor*, Report of Committee on Vocational Guidance and Child Labor of the White House Conference on Child Health and Protection, 1932, p. 10.

† *Child Labor Facts*, published by National Child Labor Committee in 1932.

taurants, as laborers and semi-skilled operatives in many kinds of manufacturing industries, as salesboys and girls, delivery boys, shipping clerks, bundle messenger and errand and office boys and girls, newsboys, garage workers, filling station attendants, porters, railroad laborers, telegraph messengers, telephone operators, servants of all kinds, bootblacks, and barbers' helpers, and almost every other conceivable type of employment. Almost all of these occupations are unskilled, mechanical, and monotonous, offering the child little opportunity to acquire either experience or skill to increase his value as an adult worker."

The relationship between child labor and the strain and hazards of industry has been recognized for some time. In 1926 the United States Children's Bureau published a report on *Physical Standards for Working Children* in which the following statement appeared:

"The minimum age for the entrance of children into industry should be not younger than 16 years. Since it is recognized that the physiological and psychological readjustments incident to pubescence (which in the vast majority of cases are not completed until the 16th year) determine a period of general instability which makes great and special demands upon the vitality of the child, it is of paramount importance that he should be protected during this period from the physical and nervous strain which entrance into industry inevitably entails. The committee recognizes the fact that pubescence may occur early or may be very greatly delayed, and is convinced that the longer it is delayed the stronger is the indication of a physical stage during which it is highly inappropriate to subject the child to the strains of industry."

The White House Conference report states that "Thousands of accidents to young workers are reported annually, many of which result in permanent loss

or loss of use of a member, in serious and permanent disfigurement, or in death. The high accident rate among young workers of 16 and 17 years of age deserves special attention. . . .

"The greater susceptibility, also, of young persons to tuberculosis is now being widely stressed, as well as the close relation existing between tuberculosis and sedentary, confining occupations, and tuberculosis and fatigue. No study of morbidity and mortality among young workers as they are related to employment has been made in recent years. The United States Bureau of Labor Statistics in a study of causes of death among cotton mill operatives, made in 1908, found that the death rate from tuberculosis among boys 15 to 19 years of age employed in cotton mills was nearly double that of boys not employed in the mills, and among girls was more than double. The installation of humidifying systems and of devices to remove lint from the air probably has resulted in an improvement in the conditions under which cotton mill operatives now work as compared with those of twenty years ago. But there is ample evidence that workers in various industries are still employed not only in places in which excessive heat or cold combined with dampness, dusty and lint-laden air, or poisonous fumes, create hazards, but in places where even ordinary standards of ventilation and sanitation are neglected."

Expert opinion of medical and health authorities is not lacking on the deleterious effects of child labor upon health and well-being. In *The Doctor Looks at Child Labor*,* Dr. Haven Emerson states that "even the school child, protected by interested and competent health supervision, suffers more severely from fatigue than from any other factor during the years of growth and development. Children in industry, whether

* Published by National Child Labor Committee in 1929.

indoors or out, show in exaggerated form damage to growth and development resulting from the still more aggravated fatigues of child labor. Competition either in agriculture or in factory production depends upon endurance and skill which only adult workers can provide without sacrifice of health."

In the same publication Dr. C. Floyd Haviland states: "Childhood is the period during which types of adult personality are determined. It is, therefore, of the greatest social importance to render conditions favorable during the early years of life for building evenly developed, well-balanced and thoroughly integrated types of personality. Child labor tends to warp, distort and inhibit personality growth, and thus too often it results in the development of malformed child personalities which are the forerunners of ill-balanced, partially integrated and poorly adjusted adult personalities. Individuals handicapped with such personalities contribute in undue measure to all the social problems with which society is confronted owing to their inability to meet adequately the demands of a complex social organization. Before the age of adolescence a child has a full-time job in learning how to live and to adjust to a world which presents many bewildering problems. A child's problems are no less real because they may not exist for the adult; and on the degree of success secured in dealing with them depends in large measure the degree of success which in later years is secured in dealing with adult problems. Child labor subjects a child to an unyielding discipline which takes no heed of special abilities and disabilities. It fails to provide the emotional satisfactions necessary to normal development. A child who is emotionally starved through child labor is one who as an adult is often found seeking denied but normal satisfactions through illegitimate means. A society which permits child labor is one

which thus feeds the future ranks of asocial and anti-social individuals."

It is therefore the direct concern of all those interested in child health to work for minimum standards of protection of children in employment. These have been very well formulated by the National Child Labor Committee.

"The National Child Labor Committee* adopts the following standards which it considers the minimum necessary to protect children against premature or otherwise injurious employment, and at the same time leave them free for adequate education, physical development and preparation for occupational life. These standards do not apply to domestic or farm work done outside of school hours in or about the home of the child's parents; abuses connected with such work are part of the problem of domestic relations and should be dealt with through parental education, compulsory attendance laws, and, where necessary, through the courts which handle matters of domestic relations or juvenile protection.

IN NON-AGRICULTURAL OCCUPATIONS

"Minimum Age—No child under 16 years should be employed except that children 14 to 16 years may work outside of school hours in light occupations. School attendance should be compulsory for the entire term for a child under 16 years unless he has completed the course of study available, and the school term should not be less than 9 months.

"Hours of Work—No person under 18 years should be employed for more than 6 days or 44 hours a week, or for more than 8 hours in a single day; and for children between 14 and 16 years the combined hours for school attendance and employment should not exceed 8 hours in a single day.

"Night Work—No person under 18 years should be employed at night dur-

* *Where Work Begins*, published by National Child Labor Committee in 1932.

ing the hours between 7 p.m. and 6 a.m., except that boys 16 to 18 years may work until 10 p.m. in suitable occupations.

"Work Permits"—No person under 18 years should be employed without a work permit based upon proof of age, employer's promise of work and a certificate of physical fitness with provision for subsequent physical examinations.

"Dangerous Occupations"—No person under 18 years should be employed in dangerous or injurious occupations.

"Workmen's Compensation"—Adult earning capacity should be considered as the basis on which wages are computed under the workmen's compensation laws for a minor permanently disabled; at least double compensation should be assessed against the employer of a minor who is injured while illegally employed.

IN AGRICULTURE

"School Attendance"—No child should be employed during the hours

when compulsory attendance laws require his attendance at school. School attendance should be compulsory for the entire term for a child under 16 years unless he has completed the course of study available, and the school term should not be less than 9 months.

"Minimum Age"—No child under 14 years should be employed at any time away from the home farm, except that children 12 years and over may engage with their parents in light tasks for a few hours a day during a short season.

"Hours of Work"—No child under 16 years should be employed away from the home farm for more than 8 hours in a single day; the combined hours for school attendance and such employment should not exceed 8 hours in a single day.

"Dangerous Work"—No person under 18 years should be employed in dangerous or injurious agricultural work; and minors employed in agriculture should be included in the workmen's compensation laws."

PUBLIC HEALTH NURSING*

Expenditures for Public Health Nursing Services in Minnesota— An analysis of expenditures of public health nursing services in Minnesota for the year ending July 1, 1932, made by the Minnesota Department of Health shows that 32 county nurses averaged \$145.50 monthly, or \$1,697.50 yearly, for salaries; their average yearly transportation cost was \$503.79, average cost of supplies \$155.03, with average total cost for the service \$2,458.67.

Sixty-three school nurses had an average monthly salary of \$167.31 and a yearly salary of \$1,505.85; their average yearly transportation expenditure was \$103.59 and supplies \$75.14; total cost of each service \$1,652.01.

Twelve community nurses received an average of \$140.85 monthly, \$1,690.25 yearly. Their transportation expenses averaged \$254.27 yearly, supplies \$152.62, and total expenses for each service \$2,027.21.—*Annual Report of Public Health Nursing Service*, Summarized by the Minnesota Department of Health, Division of Child Hygiene.

It will be interesting to see how the average expenditures for these public health nursing services during the year 1932-1933 contrast with the above figures, for it was not until the past summer that the salaries of public health nurses took such an alarming downward curve.

Health Department Nurses Are Behind Here— During the summer of 1932 a study was made of the qualifications of a selected group of Indiana

public health nurses by the Division of Public Health Nursing of the State Board of Health. The measuring rod was "Minimum Qualifications for Those Appointed to Positions in Public Health Nursing," prepared by the Committee on Education of the National Organization for Public Health Nursing and endorsed by the Public Health Nursing Section, the Committee on Training and Personnel, and the Committee on Research and Standards of the American Public Health Association. Here is the result of the study:

| | No. Nurses Employed | Per cent of Nurses Qualified |
|--|---------------------------|---------------------------------------|
| <i>Rural</i> (Nurses working alone or as supervisors) | | |
| Employed by— | | |
| Boards of education... | 4 | 50 |
| Private agencies (Red Cross, T. B. Associa- tion, etc.)..... | 44 | 40 |
| County health depart- ment | 8 | 17 |
| <i>Urban</i> (Nurses working alone or as supervisors) | | |
| Employed by— | | |
| Boards of education... | 39 | 30 |
| Private agencies | 43 | 44 |
| City health depart- ments | 11 | 1 |

The School Nurse Again— Dr. Gillihan, Health Officer of San Luis Obispo County, Calif., says "The school nurse's activities are not to be measured so much by the number of defects she may discover as by the percentage of discovered defects she succeeds in having corrected." He says, too, that the school nurse "is not the one to make these corrections, but her training is such that she makes a

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

perfect 'liaison officer' between the school with its activities, the parents with the home life, and the various agencies, public as well as private, which are interested in securing these corrections."—Allen Gillihan, M.D., School Economics, *Weekly Bull.*, California Dept. of Public Health, XI, 39:154 (Oct. 29), 1932.

Dr. Gillihan is quite right in what he says as far as he goes but he leaves the impression in this article that a school nurse's most important function is getting defects corrected. Something might be said about the need of preventing defects in the first place. This recalls what Dr. Levy of New Jersey said at one of the American Public Health Association meetings in the Child Hygiene Section—that the best time to do preventive school health work is in the infant and preschool years; which could serve as an argument for a generalized nursing service for a community instead of just a school nursing service.

However, it needs to be more widely recognized that a school nurse is concerned with more than the finding and correcting of defects. One may judge what relation this phase of her work holds to her other duties by recounting the National Organization for Public Health Nursing objectives of a public health nursing service to school age groups:

1. To assist in communicable disease control by the recognition of early symptoms and by securing immunization.
2. To assist the physician in medical inspection and in the routine periodic physical examination of every school child.
3. To assist in securing the correction of defects and in promoting health.
4. To assist in securing special examinations and such follow-up as is necessary.
5. To participate in the promotion of

hygiene and sanitation of the school plant.

6. To assist in securing proper instruction of pupils and parents in the principles of healthy living.

7. To provide or supervise adequate nursing care to all sick children.

Why Keep the Rural Nurse Rural?

—A Kentucky public health nurse tells in the *Bulletin* of the Kentucky State Board of Health why she is glad she has "stayed put" for a number of years in one community instead of becoming a transient nurse which she once dreamed she would like to be. She feels now that one lives and fulfils oneself more fully in a small circle and finds therein in miniature all she would find in a big circle.

This nurse says if she were teaching prospective county public health nurses she would tell them that it takes a nurse a year to know her county, 2 years to really know her people, 3 years for them to know her, and then she is ready to begin work.

She proves the truth of this statement in her own case by recounting how the children gathered in an isolated school house in the hills, used to run screaming from windows and doors "taking to the hills, the trees, the rocks like little wild animals whose meeting place is invaded by a panther," when the public health nurse first arrived to make school inspections. As she says, "In those days a typhoid clinic was opened with prayer and we preached a sermon for every smallpox vaccination we gave."

She contrasts this with the situation 4 years later when she finds the pupils not only eager and willing to take their typhoid and diphtheria inoculation, but parents and grandparents, babies in arms, have walked miles in a blazing sun, 300 of them, to take advantage of the preventive measures they feared so intensely 4 years ago.

She says she wouldn't have missed for anything "this gradual building up, this cautious giving of confidence," the inimitable experience of having watched the "evolution of a people's faith."—Pauline Myers, R.N., In Retrospect, *Bulletin*, State Board of Health of Kentucky, V, 3:10 (Oct.), 1932.

Here perhaps is the answer not so much to "How to Keep the Rural Nurse Rural" which was argued in nursing magazines a few years ago, as

"Why to Keep the Rural Nurse Rural." Public health nursing is educational work, and all education is slow in showing results. But part of the joy of working is seeing results—and the public health nurse who flits from place to place, even to take better positions, misses a great deal of the abiding joy of seeing obstacles in her path slowly overcome and the part she played in the "evolution of a people's faith" in public health.

EDUCATION AND PUBLICITY*

"What we need in the present emergency more than anything else is to spread among the people, and especially among the leaders, a true concept of the importance of public health in the social economy of the nation. This is obviously your duty. You, who represent the strength and leadership of the nation's health workers, must go back to your communities and broadcast the message I have just given you. Sound the alarm and arouse the public to a realization of the situation that is threatening. It is especially desirable that you win the support of your local medical societies, the chambers of commerce, the business men's groups generally, the women's clubs, and particularly the press. Make them all realize that the maintenance of the public health at high levels is vital to the public welfare."

By President Louis I. Dublin before American Public Health Association at Washington.

The New Chairman—At Washington Mrs. Mary Swain Routzahn, Russell Sage Foundation, was elected chairman of the Public Health Education Section for 1932–1933. Raymond S. Patterson, John Hancock Mutual Life Insurance Company, was reelected secretary.

Send your ideas for next year's program to either of the above.

"Health Plays For School Use"—From American Child Health Association, 450 7th Ave., New York, comes this source list of plays and material about plays in teaching health. Five mimeographed pages. A copy free. From the introduction:

Dramatic expression is so congenial to children that it is natural for the teacher to have faith in a lesson cast in such a form.

It is important, if the richness and depths of a child's imagination and emotional nature are to be permitted free expression in the interest of learning, that the lesson in play form be not only truly imaginative, but also

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Ewart G. Routzahn, 130 East 22d St., New York, N. Y.

that its factual content ring true, and that the action have, inherent in it, real dramatic possibilities.

In selecting the health plays here listed, an effort has been made to choose those most naturally childlike, most naturally dramatic.

Teachers should remember, however, that the richest vein of dramatic possibilities for learning always lies in the child himself—especially in the little child. His original dramatic expression, in words and action, of an idea that is clearly presented to him and that has become thoroughly familiar, will always have greater educational value than any dramatic activity prearranged for him by others.

What Happens To Them?—This is the cover title of a small folder from the Delaware County Tuberculosis Association, Chester, Pa. On the inside pages appears the following "obtained from a study made by . . .":

23 were dead, July 1, 1932, 4 of whom died in the County Home for the Poor.

25 are still in hospitals.

20 were living home or with relatives.

6 had removed from the county.

This is a small part of the story of the 74 persons who were listed as positive cases of tuberculosis at ONE of the tuberculosis clinics in Delaware County, Pa., in 1931.

57 Years Lost: The time recorded as lost through sickness by the 61 patients where this information could be obtained was 57 years, 1 month, 17 days.

30 Years in Hospitals: The records further showed that 30 years, 10 months, and 15 days had been spent in sanatoria and hospitals by this group of 74 patients.

Cost to County—\$100,000: The average individual wage was \$23.45 per week. Their combined earning capacity for the more than 57 years when they were unable to work amounted to \$69,646.50.

The cost of hospital and sanatorium care at \$20.00 per week for the time reported above reaches a total of \$32,040.00.

Other Interesting Facts: 9 homes were broken up; 7 patients spent time in the County Home for the Poor; 16 families had 23 previous deaths from tuberculosis; 1 patient had recovered sufficiently to work full time; 6 were working part time; 181 patients were listed for State Sanatoria from Delaware County in 1931. Of this number about 20 per cent were children sent to preventoria.

As H.E.K., who sent it to me, says: "It is a bully idea, though some improvements could be made," especially in the lay-out of the original folder.

Quite different is the 8-page booklet from the Anti-Tuberculosis Association of Jefferson County, 2019 Ave. F, Birmingham, Ala.

"Facts and Figures About Tuberculosis in Jefferson County," the cover title, is not so good. The inside pages are headed: "The Gist Of It," "A Problem," "A Vision," "A Great Task," "A New Outlook." Well localized copy "which has been prepared primarily for the use of leaders in various groups." Very simple line sketches lighten the pages.

Grand Stand Seats For a Great Campaign—What may become a most extensive campaign of agitation and presentation touching the health field has just now been launched. The final report of the Committee on the Costs of Medical Care has sharply drawn the issues, and they will be capably laid before the country. Whether or not there is a continuing body, the vast interests involved will provide a self-sustaining public discussion of considerable vigor. It will be of value to health educators to observe from the beginning the growth of public opinion wherever it may go, whatever direction it may take.

Any number of folders describing the final report will be supplied free by University of Chicago Press, 5750 Ellis Ave., Chicago.

Where Is It in the Report?—Where is health education mentioned? Few department reports give adequate indexing to health education activities.

In one state department report "educational work" is mentioned under "Maternity division"; "public health education" under "Public health nursing division"; "educational activities,"

"articles published," and "lectures" under "Social hygiene division"; "educational activities" under "Tuberculosis division"; and then a number of sub-headings under "Public health education division." Likewise "research" and "studies" are merely sub-headings under different titles. Research workers, writers and others desiring to gather material from departmental reports will surely miss much material, unless they can take the time to dig through indexes or run through long reports, since many reports lack even inadequate indexes.

Is it not worth while to study how to make the contents of annual reports more usable by citizens and public health workers?

Journalism Students Writing Up Nurses—The American Nurses' Association reports a plan which health workers might try in any city or state which has a school of journalism.

All women members of the feature writing class at New York University School of Journalism have been assigned an interview with some nurse whose work is of more than local interest and importance. Professor Helen Scott Mann, who is in charge of the course in feature writing, will assist the students in placing their interviews in Sunday or daily newspapers in the communities covered.

State, district and alumnae associations are asked to name nurses and nursing services worth publicizing either locally or nationally. Names of individual nurses, together with a few facts about their experiences, hobbies, or backgrounds, should be sent to the Department of Public Information, A.N.A. If some approaching event will soon bring these women into prominence that should by all means be mentioned, as timeliness is a big factor even in the human interest or the interview type of newspaper or magazine article.

Is Men's Clothing a Health Problem?—"In Germany, while a dog's hair in winter represents only 1.4 per cent of its total weight, the winter clothing of a man represents about 10

per cent of his total weight," according to a statement from the League of Red Cross Societies, Paris. Is this heavy weight of clothing, by itself or in relation to the lighter weight of women's clothes, a factor in colds?

Discussion, Discussants and Discussion Leaders—Recently all chairmen of divisions of the National Conference of Social Work have received a "Handbook" of 44 mimeographed pages. Since many readers of this department are interested in planning and conducting meetings some quotations of what is said about discussion should be of interest.

The use and value of discussion—When planning the program for an individual meeting the Division Committee should definitely decide in advance whether it wishes discussion and what kind of discussion, and plan definitely for it. A discussion is valuable as it brings out various points of view, criticisms of the material presented or through the use of questions permits the speaker to make clearer some point in his paper or address that perhaps was not cleared up in the formal presentation. It also stimulates new constructive thinking and provides the means for the participation of a larger group in the Conference. Much of the value of discussion can be lost unless careful preparation is made.

Place of the Discussant or Commentator—For the purposes of the Conference let us define the discussant as a person who is asked in advance to discuss a particular paper. This person should have access to the manuscript he is to discuss at least three weeks in advance of the Conference. He should confine his remarks to a discussion of that paper rather than the presentation of additional material. As one studies past programs one finds that frequently people asked to comment on a given paper use this opportunity to present an entirely different subject or material that has very little relation to the paper presented. When a person is asked to discuss a particular paper definite time limits should be given and some indication as to the particular contribution desired from the discussant. Every effort should be made to see that he has a copy of the manuscript in ample time to prepare his part of the comment before the Conference.

It may be desirable, at long intervals, to have the full period following a speech (or

several speeches) wholly taken up by discussants who present different points of view or relate different experiences bearing on the subject.

In any case Discussants should not be called Discussion Leaders, or that period of time used by discussants labeled as Discussion.

Ethics In Hospital Publicity— An extensive "Report of the Committee on Public Relations," American Hospital Association, 18 East Division St., Chicago, reviews the publicity problems of the hospital, and the use of the principal media. "The committee believes that the submission of the following principles will guide hospitals and similar institutions in carrying on what may be regarded as ethical publicity":

Publicity by clinics, hospitals, sanatoria, and other semi-public medical institutions as to quality of work done implies unusual and exceptional ability and efficiency on the part of their professional staffs, and therefore is advertising of the medical men concerned. This type of advertising distinctly savors of quackery and is unethical.

Publicity by any such institution stating or implying that by reason of its exceptionally fine equipment and material resources it is able to, or does, give the public better medical service than similar institutions are able or willing to render, is advertising for purposes of self-aggrandizement. Statements of this type are frequently exaggerated and misleading and are detrimental to the best interests of the public, of the institutions concerned, and of true medical progress.

From time to time, hospitals, sanatoria, and other similar medical institutions must raise funds from an interested public for capital expenditure and maintenance. Furnishing the public with facts concerning such an institution, its work, its aims, and its ideals is legitimate and desirable. The public is interested in these facts and therefore is entitled to know them. Publicity dealing with these facts is ethical, provided, of course, that it refrains from any comparisons or superlative terms either direct or implied.

Publicity carried on by any one institution should be such as will be beneficial to all like institutions in the community. It should tend to develop public confidence in hospitals, sanatoria, and other medical institutions. It should be free from superlative or

comparative statements and any implication of rate-cutting or unfair competition.

The report includes nearly 5 pages of bibliographical references to material which has appeared in hospital publications. 40 pp. 75 cents.

What Will You Do About It?— Every worker in health education is threatened with a reduced budget, yet the need for health education is as great as ever. *What will you do about it?* And what might the Public Health Education Section do to help you?

How About Third Class Mail?— Have we carefully examined the possibilities? Many large business houses have been testing first class versus third class. A number of them have found that third class serves many uses as well as first class. A number of them assert that they will continue to use much third class even when first class is reduced to two cents.

Printed, multigraphed, or mimeographed matter may go at third class at 1½ cents for two ounces or fraction thereof. If an official permit is secured the same material will go for 1 cent—if mailed in lots of 20 lb. or not less than 200 pieces of the same kind. This permit privilege calls for sorting geographically outside of the mailing city, and the mail must be mailed at the post office and not dropped into a mail box.

The "postage saver" envelopes are safe and need not look cheap. There are plenty of good looking envelopes on the market.

Printed or duplicated letters sent third class may be signed and individually addressed just like a first class letter.

The simplest personal touch may be given by pen-writing "Dear Mr. Smith" (or whatever the name is) at the top. But some very successful advertisers are using the letter form, without being individualized.

To get the 1-cent rate any single lot of 200 or more pieces must contain the same enclosures.

What Is Health Education?—

Annette M. Phelan presents some attitudes and principles in health education in the school, and tells us that

Health Education is a way of living, mentally, emotionally, socially, and physically. It enters into and grows out of all child experiences in the school, the home, and the community. Health is a means to human happiness and achievement and is best thought of as such—not as an end in itself.—

"Health Education For All." *Public Health Nursing*, 450 7th Ave., New York. Dec., 1932. 25 cents.

"Yes? What's the Name?"—

Such a telephone greeting does not foster good will for a health agency—depression or no depression. Says A. M. Lockhart in *The Rotarian* (Dec., 1932):

After all, telephone calls are substitutes for personal calls. The operator is merely removed from the sight of the person calling. The contact is otherwise personal. The telephone switchboard is indisputably one of the most important outposts of a firm's contact with the outside world. It's the port of entry for the majority of the total contacts a busy man makes during a day's work at his office.

The stewardess of a switchboard functions as a reception committee of one—there to greet, if you please, all the callers who visit by means of the telephone. She is thus in excellent position to make or break a lot of good will.

A writer in *Printers Ink* (Dec., 1932) telling of some experiences by three business men calling at certain offices comments on the good or bad services by several information clerks.

As Mr. Lockhart says: "Receptions of this sort aren't limited to commercial houses, mind you. Secretaries of many professional men are similarly wanting." Might he have included health departments?

At the Foot of the First Column—We discover numerous readers who don't know where to address the editor of this department. Please turn to the first column of this department in any issue of the *Journal* and read the footnote. Whenever you think of it please send your material direct to that address. Then the A.P.H.A. need not spend extra postage in forwarding the material to the editor of this department.

REPORTING

"Bibliography for the Year," in Annual Report of New York State Dept. of Health, is a record of articles by staff members published in various periodicals.

Some of the page headings in a pamphlet describing and illustrating a hospital: "The Patient an Honored Guest," "The Comforts and Care of Home," "Keeping Down the Cost," "Baby Starts Life Right," "Human Skill in its Highest Attainments," "Economy and Efficiency of Operation," "For Correct Treatment of Disease or Injury," "The Convalescent Patient is Constantly Encouraged," "Correct Foods—Properly Cooked—Served Hot." In "An Ideal Hospital," Presbyterian Hospital of Colorado, Denver.

The 1932 "Year Book" of the United Hospital Fund of New York City, 122 East 22d St., New York, carries explanatory statements with all photographs, such as:

Insulin Keeps Men At Work: Every year hundreds of breadwinners, who would otherwise be helpless invalids, are able to keep on the job with the help of free insulin treatments.

TIMELY TOPICS

"Forty Million Babies," the world's annual crop, with application to services rendered by *New Haven* to its share of that total. *Health*, Dept. of Health, New Haven. Sept., 1932.

"Poor Eyesight Causes Family Rows," by David Resnick. *Everybody's Health*, St. Paul. Oct., 1932. "Eye hazards to avoid in the home."

Poliomyelitis is given chief attention in Nov., 1932, issue of *Canadian Public Health Journal*, Toronto. 25 cents.

"Man Controls Germs, Runs Amuck Himself." *Illinois Health Messenger*, Springfield. Nov. 15, 1932. Disease vs. automobile deaths.

"Danger to Health in Christmas Hysteria," by Thomas Myers, M.D. *Everybody's Health*, St. Paul, Minn. Dec., 1932. 10 cents. "Nervous, physical collapse and disease epidemics often follow unwise holiday celebrations."

"A Half Century of Change," *Illinois Health Messenger*, State Dept. of Health, Springfield, Ill. Dec. 1, 1932. Changes in occupation, and "a change no less profound and far reaching than that of occupation, but for a different reason, has taken place in respect to the hazards of health and the causes of mortality in Illinois." May be adapted to other states and to cities.

PUBLICITY PRESENTATION

The Illinois Conference of Public Health Officers and Nurses, Dec. 15-16, 1932, included these topics: "The Public Health Job of the Parent-Teacher Association," "Non-professional People in Public Health Work," "Educating the Public in Health Matters" (Dr. W. W. Bauer), "Utilizing Organized Groups in a County Nursing Program."

"Popular Health Education vs. The Medical Charlatan" was presented at

New Jersey Conference of Social Work by American Social Hygiene Assn.: "Can We Be Duped?" and "Campaigning Against Quackery."

Dr. Iago Galdston conducted a clinic on public speaking before the Social Work Publicity Council, Detroit, Nov. 8.

In *New Mexico Health Officer*, Bureau of Health, Santa Fe (Oct., 1932), Eleanor L. Kennedy, says:

The object of publicity in public health nursing is to show the people what the nurse is doing for the improvement of their health in such a way that they've just got to help her and support her work. In addition, the knowledge of your work educates the people to a higher estimation of the value of health to themselves, and as a community responsibility.

DEPRESSION

"The Health of the People in a Year of Depression," by Dr. Louis I. Dublin. *American Journal of Public Health*. Nov., 1932. A presidential address.

"The Menace to National Health," by James A. Tobey. *Current History*, New York Times Bldg., New York. Dec., 1932. 25 cents. The conclusions of the article "may seem pessimistic, but they should be regarded as a warning not to jeopardize the health of the nation."

"Unwise Economy May Affect Future Health," Dr. S. W. Sayer, New York State Dept. of Health, Albany. Radio talk. Enclose 3 cents.

"Health Service Vital," a one-page statement of need of maintenance of health departments. Oregon State Board of Health. Nov. 22, 1932.

Depression cartoons appearing in the Health Bulletin Service of the A.P.H.A. have been used in various parts of the country.

BOOKS AND REPORTS

Alcohol and Man—*Edited by Haven Emerson, M.D.* New York: Macmillan, 1932. 451 pp. Price, \$3.50.

This volume presents many of the same difficulties for a review as *Prohibition: A National Experiment*. It consists of a series of articles by 22 authors, most of them men engaged in the sciences connected with biology and medicine. Others are connected with life insurance companies and statistical bureaus. Every question is treated apparently without bias, and facts, as brought out by scientific experiment, are given. We wish it were possible to give quotations at some length.

The conclusions of the authors as a group are fairly represented in the preface which, under the circumstances, make the best review that can be given. It is agreed that education in the basic facts concerning alcohol is essential to the best interest of man and his social organization; that there is much need of rewriting the texts and courses in physiology, hygiene and health offered to the children of the country in so far as the teaching of the effects of alcohol on man is included in state laws, or by regulation by boards of education; that an obligation rested on the contributors to assemble and present for the use of the educated laity facts concerning alcohol in its biological and human relationships, and that throughout the text, facts and opinions should be supported by available references, regardless of their bearing upon the current controversies as to the wisdom or desirability of continuing the 18th Amendment.

The authors have avoided the use of terms implying bias on one side or the other, and state that in no instance have they been aided financially, or supported in any way, by either the

advocates or opponents of federal prohibition or of the liquor trade. They have included an excellent article by Drs. Langmead and Hunt of England on the effect of alcohol on the body's resistance to infection. The names of the writers of the various chapters give assurance that they are authoritative and embody the latest and most accurate results of research.

It is hard to speak too highly of this production. It comes at a time when exact knowledge will be of great value, though as pointed out by the editors of *Prohibition: A National Experiment*, the question of legal control is not likely to be settled on scientific evidence. However, exact knowledge must have an influence, even on the biased and emotional. We believe the volume will be of especial use to physicians and social workers, and we hope that those entrusted with the formulation of laws and regulations will also study it. For the doctors, the chapters on the physiological effects and therapeutic use of alcohol will be of particular interest.

The make-up of the book is excellent; and a good index of authors as well as one of subjects adds to its value.

MAZÛCK P. RAVENEL

Prohibition—A National Experiment—*Edited by James H. S. Bossard, Ph.D., and Thorsten Sellin, Ph.D.* Philadelphia: American Academy of Political and Social Science, 1932. 269 pp. Price, \$2.50 (cloth), or \$2.00 (paper).

The question of the use of liquor will not down. The Democrats have declared openly for repeal of the prohibition law. The Republicans declared that present conditions could not continue, which was paramount to acknowledging the failure of prohibition as it

now stands. Under any circumstances, the question is a live one in both parties, and there is no question that strenuous efforts will soon be made to repeal the law. The result will be many and long discussions for and against the use of liquor.

The volume before us is an attempt to get at some of the underlying facts. For some 10 years the American Academy of Political and Social Science has published articles on the subject.

This book does not lend itself readily to review, containing as it does articles by 24 authors, ranging from Deets Picket and Clarence True Wilson on the one hand, to Rufus S. Lusk on the other. Several are written by men connected with the Bureau of Prohibition, for example, "The Illegal Liquor Traffic." It is possible to accept the statements as being correct as far as official records go, but as it is well known that there is no record of the illegal traffic—and that is what we are principally concerned in at the moment—it is manifest that the estimates are more than likely to be very far from the truth. On the one hand, Mr. Woodcock, Director of Prohibition, estimates the annual consumption of liquor at 800 million gallons, while the Association against the Prohibition Amendment estimates it at 1,100 million. The same difficulty exists in regard to the illegal traffic in narcotics. Other articles are from those who have no reason for bias, but there is conflict of opinions, and the best that can be said of most of them is that they are opinions, however sincere the authors may be, or however much they believe in the facts or alleged facts on which their ideas are based.

The editors in their "Foreword" tell us what we all know—that there are no complete statistical data available for a conclusive analysis of the effects of prohibition; that the question will probably never be settled by scientific

treatment; and that the whole question is bound up with emotional attitudes which make dispassionate and scientific treatment difficult. However, whatever we may think of these discussions, and whether we believe all of them to be sincere or not, they furnish interesting reading and bring up many questions which those interested in temperance must consider.

Perhaps the most valuable part of the book consists of the 5 articles concerning the control of liquor in Canada, Great Britain, Sweden, Finland, and Russia. The medical articles concerning mortality and morbidity and mental hygiene are among the best and most useful. It is interesting to note the conclusion of unbiased writers that prohibition has had less effect on economic welfare—favorable or unfavorable—than is claimed either by its supporters or opponents; that it is extremely difficult, if indeed possible, to establish any direct relationship between modification of the 18th Amendment and the general agricultural situation; that no definite conclusion can be arrived at as to the direct part played by prohibition in increasing crime; that while there was a marked reduction in alcoholic psychoses in 1919–1920, there has been a notable increase in such psychoses as well as deaths since 1920, and an even more notable increase in alcoholism without psychosis, during the past 5 years.

This volume can be heartily commended to all who are interested in this subject—and what thinking man is not at this time? MAZÛCK P. RAVENEL

Principles of Chemistry—By J. H. Roe. (3rd ed.) St. Louis: Mosby, 1932. 486 pp. Price, \$2.50.

Elementary science courses are a recognized part of the early training of student nurses. The difficulties in selection and presentation of suitable material can be appreciated fully only by those who have attempted to give

such courses. Criticism of any text prepared for the above purpose is not easy to make.

This book contains sufficiently complete discussions of a few elements—hydrogen, oxygen, and nitrogen, and very brief mention of a considerable variety of inorganic compounds quite apparently chosen because they are likely to be encountered, at least in name, by nurses. Organic chemistry has not been neglected. Chapters dealing with carbohydrates, proteins, fats, and vitamins, are followed by discussion of foods and nutrition and secretions and excretions. A course of laboratory experiments is included. The author has done an almost impossible task in a distinctly acceptable manner.

JOHN F. NORTON

Mental Deficiency Due to Birth Injuries—By *Edgar A. Doll, Ph.D., Winthrop M. Phelps, M.D., and Ruth Taylor Melcher.* New York: Macmillan, 1932. 289 pp. Price, \$4.50.

This is a timely volume which sets forth in well-balanced chapters the various factors contributing to injury of the nervous system incidental to childbearing. At present so much attention is being focused upon maternal and neonatal mortality that we are apt to overlook the serious damage due to birth injury in those who survive. Injury at birth is one of the prime factors in early infant mortality. Undoubtedly it also is the cause of a considerable number of cases of motor paralysis and mental retardation; "although they constitute but a small proportion of all mentally deficient children." The authors state that the risk "is especially serious among first born children, is present in an apparently normal birth as well as in those where natural labor is unusually severe or prolonged, and in those which require instrumental delivery."

The introduction and the chapter on Etiology indicate the varieties of injuries, the predisposing and causative factors, and the symptoms of intracranial injuries. The carefully selected case studies are particularly helpful in understanding the location and extent of the damage which may follow severe birth injuries. Chapters on Mental Tests and Measurements, Mental Estimates, and Mental Growth round out the volume. A practical consideration of physical therapy also is given.

The high quality of printing and illustrations of the Macmillan Company is maintained in this volume.

RICHARD A. BOLT

Medicine and the State. The relation between the private and official practice of medicine with special reference to public health—By *Sir Arthur Newsholme, K.C.B., M.D., F.R.C.P.* Baltimore: Williams & Wilkins, 1932. 295 pp. Price, \$3.50.

This book is the fourth and final volume of a series of "International Studies" conducted by the author for the Millbank Memorial Fund. It is, however, to a very considerable extent, independent of the other three volumes, although, necessarily, many of the conclusions expressed in this volume are based on facts published and analyzed in the previous volumes.

Briefly, the author reports the results of his survey of the existing relations between the practice of medicine in all of its branches and the activities of the various governments concerned in Western Europe with regard to the medical care of their peoples. In this connection he gives special consideration to four groups of medical services, which constitute the most recent advances in public health, i.e., the medical care of maternity, child health, and the treatment and prevention of tuberculosis and venereal diseases.

The operation of hospitals and clinics with special reference to their relations with the medical profession on one hand and the public and the state on the other is discussed at length. The chief varieties of medical practice, including group medicine, state medicine and insurance medical practice, are reviewed, analyzed and criticised. The author maintains emphatically that the health of the individual citizen is a communal as well as an individual concern. He concludes that the developments in medicine have been such as to require close coöperation between general practitioners and consultants. He also finds that the official phases of both prevention and treatment should come under a single directing authority.

Sir Arthur Newsholme is peculiarly well fitted to investigate and discuss the extremely important and pertinent subject of the relations between medicine and the State. His years of experience in health work in England, his varied contacts with the practice of medicine in his own country and abroad, and his knowledge and experience with social and governmental problems have gained him unexcelled qualifications for this work.

In some instances, the views expressed by the author might be regarded as open to criticism when applied to conditions in America. Nevertheless while the problems considered are those existing in Western Europe, still any health officer in this country should find in this book much food for thought and numerous sources of inspiration in dealing with the many administrative activities involving the private practitioners.

GEORGE C. DUNHAM

Industrial Psychology — *Morris S. Viteles*. New York: Norton, 1932. 652 pp. Price, \$5.50.

The subject of industrial psychology continues to engage increasing attention, as the present extensive volume of

rather closely written pages, numerous tables, figures, and a limited number of photographs shows. We have already reviewed in these pages more or less similar works by the Gilbreths, Scott, Anderson, Burt, Hill and others, and are pleased to receive this work from an academician who has had years of industrial experience of consulting and research nature in connection with various leading industries in the United States, and who combines an extensive European literature with that of American origin.

In the twenty years since Münsterberg presented the first systematic formulation of the problems and scopes of an industrial psychology, there has become available a wealth of experimental data and concrete achievements in increasing the effectiveness and happiness of man in industry. The present work reviews the new technics, new equipment, and new viewpoints, and discusses many of the fundamental problems of general and applied psychology as well as the relation of these to the industrial situation.

The work is divided into three main sections: The foundations of industrial psychology, fitting the worker to the job, and maintaining fitness at work—the total comprising 27 chapters. The plan has been to develop the subject somewhat in its historical aspects, to integrate industry and psychology, and to stress the inseparability of the two. Both manual and mental occupations are considered as well as the modifications which physiological and environmental influences introduce. The chapters on motives in industry, the maladjusted worker, and problems of supervision are monographic in themselves. There is a breadth and comprehensiveness about all of the subjects treated which is both informational and edifying, and throughout tempered with commensurate conservatism.

Written by one who is not only en-

thusiastic but thoroughly familiar with the scope and trend of his subject, the book lends itself to personnel, medical, and health specialists and all who are interested in efficiency from the human element standpoint.

Fortunately the numerous citations and acknowledgments appear both on the respective pages and in separate lists alphabetically arranged at the rear of the volume, to which an extensive subject index is added. The work is dedicated to two outstanding teachers at the University of Pennsylvania—Witmer and Twitmyer—while the publishers are to be commended on quality, style and format.

EMERY R. HAYHURST

A Text-Book of Human Physiology for College Students—*By August Krogh, revised and edited by Katherine R. Drinker. Philadelphia: Lea & Febiger, 1932. 233 pp. Price, \$2.75.*

This small textbook originally published in Danish in 1908 is now reëdited and translated into English for the use of college students. A concise account of the physiological functions of the body is given in 13 short chapters and 83 experiments are outlined in the appendix for the elucidation of the subject matter of the text.

The opening chapter deals with the Chemical Constituents of the Human Organism and is followed by one on the Digestion and Absorption of Food. Each succeeding chapter is a logical outcome of the preceding one and profuse illustrations, the majority of which are taken from standard textbooks, contrive to make the book complete in itself. In the later chapters the physiology of the nervous system and of the special sense-organs is outlined.

Some statements could with advantage be improved; for example, solutions of polysaccharids (p. 20) and

a solution of protein (p. 22) are said to be "slimy," and again "sugar passes unchanged through the (intestinal) epithelium" (p. 44). Less ambiguity would result if the word "dextrose" were substituted for sugar.

The book contains useful information, is excellently printed and may confidently be recommended as a suitable introduction to larger text-books on the subject.

JOHN WYLLIE

Pulmonary Tuberculosis—*By Maurice Fishberg. (4th ed.) Philadelphia: Lea & Febiger. 1191 pp. Price, \$15.00 for 2 Vols.*

This book, in 2 volumes, is the best book now on the subject in the English language. Over 300 pages and over 100 new illustrations, largely roentgenograms, have been added. Etiology, pathogenesis, symptomatology, roentgenology and clinical forms are in the first volume.

One of the great assets of this book is the frankness and courage of the author. He questions whether the great modern antituberculosis campaign has really accomplished anything worthy of note. The number of the infected is no less today than 30 years ago. Again the tuberculosis mortality rates follow closely the general mortality rates.

His discussion of the tubercle bacillus is excellent, but mentions dissociation only under BCG. He still affirms that tuberculous exogenous (?) infection can occur only once and entirely sweeps aside the view, now widely held, that exogenous reinfection by inhalation is the usual cause of phthisis. The chapter on roentgenography is well done, and wisely illustrated. The importance of this method in the diagnosis of many lesions, the extent of the lesions, and their relations to the physical signs, is well brought out.

The second volume begins with the disease in children, points out that

the roentgenogram is of less value in diagnosis in infantile than in childhood tuberculosis, and of no practical value in the diagnosis of complicating intestinal tuberculosis. He finds heliotherapy of no value in the treatment of this condition. So much evidence has accumulated in this country and Europe to show that he is mistaken that it is only necessary to mention it as a blemish in a good book. Pregnancy is of little moment in arrested tuberculosis. Insulin in ordinary doses, he thinks, may cause focal reaction which the reviewer has not noted.

The reader is left to infer that some danger lurks in the immunizing use of BCG. Heliotherapy may provoke unwelcome reactions but the reviewer has never noted it in any case of pulmonary tuberculosis following the use of the ultra-violet ray lamp. Gerson's salt-free and high vitamin diet has no scientific foundation, he thinks, and no effect on the pulmonary disease. He attributes no value to tuberculin and sanocrysin.

The surgical treatment of the disease is fully dealt with, and here also his experience leads him to views different from those held by many. He cautions against too prolonged collapse of the lung in artificial pneumothorax and opposes the very beneficial operation of intrapleural pneumolysis. He leads one to infer that thoracoplasty does little more in many cases than prolong life. He dwells upon the dangers of oleothorax.

The reviewer differs from the author in many instances but he has found the book refreshing in its frankness and stimulating in its discussions. There is some suggestion that personal likes and dislikes have crept in here and there. For those engaged in public health work, we can heartily recommend many chapters in the first volume, for even when some statements are unorthodox—and they are not infre-

quently so—they lead to the clarification of the faith that is within one. The book represents a vast amount of study and a great clinical experience, though at times one is led to wonder if it has not been drawn a little too much from the more advanced cases. Every worker in tuberculosis should have access to these valuable volumes at all times. LAWRASON BROWN

Principles and Methods of Sociology
—By James M. Reinhardt and George R. Davies. New York: Prentice-Hall, 1932. 685 pp., Price, \$3.50.

Nothing illustrates the ill-defined character of sociology as a scientific discipline better than the extraordinary differences in the treatises pretending to set it forth in a systematic and fundamental manner. The above work is in this respect in line with expectations. Like most others also it has its own special claim to uniqueness and to attention. Without defining sociology, it presents in Part I, social process, some study of methods and an extended treatment of conflict and coöperation. In Part II attention is devoted to Factors Conditioning Society, and in Part III to Institutional Aspects of Society. The topics in these last two parts are those now commonly included in elementary college texts. The treatment is topical and systematic rather than exhaustive and original, being designed to give a comprehensive orientation to the student.

The authors tell us in the Preface:

Primarily it is a philosophy of history in which a new interpretation of economics derived from statistical and mathematical analysis takes the central place. It sees the "residues" (after Pareto) of the historic process largely in terms of the economic consequences of trade relations.

This is a too ambitious statement of the actual achievement, for this philosophy is far from systematic state-

ment in the text. Nevertheless, this viewpoint serves to explain the numerous very interesting statistical studies inserted throughout the text. These are done with a neatness and clarity that could not be surpassed. If they seem at times to be thrust into the text at points that appear to me merely the most convenient rather than the strictly logical ones, they will nevertheless be generally widely approved not merely as contributions to our understanding of social phenomena but as excellent teaching devices. By means of them the beginning student will learn what is meant by a correlation coefficient and something of how it is found.

F. H. HANKINS

Child Labor. *Report of the Subcommittee on Child Labor of the White House Conference on Child Health and Protection.* New York: Century, 1932. 592 pp. Price, \$5.00.

In this report there has been brought together, for the first time, all available material bearing upon the subject of child labor in the United States. The data has been assembled largely from reports of previous studies and surveys published from time to time by the United States Children's Bureau and the National Child Labor Committee. Unfortunately it was not possible to obtain the census figures for 1930, as undoubtedly there have been certain changes in industrial and geographical distribution since 1920.

The volume is arranged conveniently for reference purposes. It contains an exhaustive bibliography and an excellent index. Part I considers the non-agricultural occupations with detailed analyses, a general summary, and recommendations. Part II is devoted to employment of children in agriculture. Part III clearly depicts the hazardous occupations and discusses industrial accidents and the administra-

tion of workmen's compensation. This subject is continued in Part IV, where more detailed consideration is given to the administration of laws affecting employment of minors. Recommendations for employment certificates, school attendance, and industrial inspection are given. The concluding part is composed of supplementary reports, which include the New York law on employment of children in theatrical performances and the physical condition of children entering industry in a number of cities.

This volume is a good reference book for those who desire a clear idea of what the child labor movement in this country really means.

RICHARD A. BOLT

Body Mechanics: Education and Practice. *Report of the Subcommittee on Orthopedics and Body Mechanics.* Robert B. Osgood, M.D., Chairman. *Publication of White House Conference on Child Health and Protection.* New York: Century, 1932. 166 pp. Price, \$1.50.

This report has assembled a great deal of scattered material on body mechanics in relation to physical fitness and health of children. The term body mechanics is preferred to that of posture, which the committee feels has a more limited and less precise meaning.

Body mechanics may be defined as the mechanical correlation of the various systems of the body with special reference to the skeletal, muscular and visceral systems and their neurological associations. Normal body mechanics may be said to obtain when this mechanical correlation is most favorable to the function of these systems.

It is pointed out that poor body mechanics may be developed very gradually and their immediate effects not noticed on account of partial or complete compensation. The various factors contributing to poor body mechanics are discussed.

About half of the volume is taken up by a reprint from the United States Children's Bureau on *Posture and Physical Fitness* by Dr. Armin Klein and Leah C. Thomas. The appendix contains also a reprint from the Boston Public Schools on a *Course in Physical Education for the Day Elementary and Day Intermediate Schools*.

The report cautions against accepting any one type of individual or group of individuals as the standard norm for good body mechanics. Different types of body build should be compared and evaluated. Detailed recommendations and suggestions for corrective exercises are set forth, which are of value in guiding those concerned with the growing child.

The Sub-committee concludes that

. . . further investigation and larger and longer surveys are most to be desired, but the Sub-committee is of the opinion that the evidence presented strongly suggests that there exists an intimate association between good body mechanics and good functional health and between poor body mechanics and poor functional health, and that this association may well represent a causal relation in many instances.

RICHARD A. BOLT

Environmental Factors in Negro Elementary Education—By Clark Foreman. New York: Norton, 1932. 88 pp. Price, \$1.00:

The place of environmental factors in conditioning results of educational achievement tests is recognized by most psychologists. In this treatise the author has presented a description of environmental conditions which he believes profoundly modify the educational achievement of negro children in southern elementary schools. He concludes from the data collected that evidence exists to the effect that as the environment of negro children approaches in similarity to that of white children they approximate the norm of white children in educational achieve-

ment. The significance of health as a factor is admitted (pp. 50-55) but the difficulty of securing evidence as to the effect of health conditions on achievement compels the author to dismiss this consideration with little attention. This volume should be of interest to students and other workers in the field of negro education.

FRANKLIN O. NICHOLS

An Introduction to Practical Bacteriology—By T. J. Mackie and J. E. McCartney. (3rd ed.) New York: Wood, 1931. 421 pp. Price, \$3.50.

This book measures up fairly well to its subtitle, namely, "A Guide to Bacteriological Laboratory Work." Although it is only 3 years since the second edition appeared, the authors have subjected the book to a rather thorough overhauling. Some of the material of the former edition has been omitted and considerable new information added. Having the needs of the junior student in mind, the text has been divided into large and small type matter, the first having to do with the more essential and fundamental part of the subject.

With the exceptions of a few diagrams, illustrations are omitted, the book being intended as a guide in a laboratory course where the various apparatus, microscopic appearances, cultural characteristics, biochemical and serological reactions, are adequately demonstrated. An attempt is made to emphasize the more important methods used in routine bacteriological diagnosis, those which the authors have found most serviceable being recommended. Due attention has been given to the diagnosis of tropical infections.

This publication has value other than as a guide, for it deals rather freely with principles. Both the general student and the practitioner will find it useful, although it was written more especially for the bacteriologist. C. F. ADAMS

Proceedings Sixth Annual Conference, The Maryland-Delaware Water and Sewerage Association, Cumberland, Maryland—1932.

The proceedings of the Sixth Annual Conference of the Maryland-Delaware Water and Sewerage Association contains a valuable symposium on stream pollution control in which the laws,

policies, accomplishments, cooperative studies, agreements and the like in the states of Delaware, Pennsylvania, West Virginia, and Maryland are explained and amplified. Other papers discuss the admission of industrial wastes to sewers, the influence of soils, rocks and minerals upon water potability, activated carbon, and a new dam. A. P. M.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Symposium on Dentistry and Health—This series of papers discusses the relations of dentistry and nearly every specialty in medicine, ending with the health triangle, "physician, dentist and patient."

ATKINS, R. T. *et al.* Diseases of Common Interest to the Dentist and Oto-Laryngologist. New York State J. Med. 32, 21:1221 (Nov. 1), 1932.

Undulant Fever in Ireland—In a series of papers the status of *Br. abortus* infection, in man and animals, and its spread through milk are presented at length.

BIGGER, J. W. *Br. Abortus* Infection in Ireland. J. State Med. 4, 11:642 (Nov.), 1932.

Influenza Results—During epidemics of influenza the death rates for diseases other than influenza and pneumonia (about 40 per cent of the excess mortality) rise to present a picture strikingly similar in time distribution to the curve of the influenza and pneumonia rates. Excess deaths in which influenza was given as a contributory cause account for only half the increase.

COLLINS, S. D. Excess Mortality From Causes Other Than Influenza and Pneumonia During Influenza Epidemics. Pub. Health Rep. 47, 46:2159 (Nov. 11), 1932.

Practical Mental Hygiene—Traveling diagnostic clinics in Massachusetts have accomplished the tremendous job of giving mental examinations and diagnoses to 41,000 mentally retarded school children. The value of this work to society must be great.

DAYTON, N. A. The Walter E. Fernald Plan for the Examination of Retarded School Children. New Eng. J. Med. 207, 21:914 (Nov. 24), 1932.

Future Medicine and Health—The long awaited final report of the

Committee on Costs is summarized. The recommendation for publicly supported hospital centers providing medical services for all will not warm the hearts of those, like this reviewer, who don't like hospitals, and who want the comfort and security of the family doctor. However, the insistence upon really adequate health services will receive a loud Amen.

EMERSON, H. Medical Care for All of Us. Survey 68, 17:629 (Dec. 1), 1932.

Plague in Peru—Study of many years of endemic plague in Peru reveals that the incidence is greatest in cities in which the rat harborage of buildings is worst, regardless of climatic location. The value of rat proofing is well illustrated.

ESKEY, C. R. Epidemiological Study of Plague in Peru. Pub. Health Rep. 47, 47:2191 (Nov. 18), 1932.

Dental Caries—We learn in the first of these two papers that caries is a "saprophytic phenomenon occurring in morphological fissures, developmental enamel faults, or in the permeable necks of teeth," and that the prevention of decay can be accomplished only by rendering the mouth unsuitable to the saprophytes concerned or by breeding a race free from crevices, faults and receding gums. The second paper outlines the dietary principles now generally accepted by hygienists.

FISH, E. W. and MELLANBY, M. Aetiology of Dental Caries. Brit. M. J. No. 3746 (Oct. 22), 1932.

Amebic Dysentery—House flies may be a factor in the spread of *E. histolytica* in the community studied, but none of the animals closely associated with man act as reservoir hosts, or assist in the transmission of, the parasite. So concludes an interesting study.

FRYE, W. W. and MELENEY, H. E. In-

vestigations of *Endamoeba Histolytica* and Other Intestinal Protozoa in Tennessee: IV. A Study of Flies, Rats, Mice and Some Domestic Animals As Possible Carriers of the Intestinal Protozoa of Man in a Rural Community. *Am. J. Hyg.* 16, 3:729 (Nov.), 1932.

School Health Results—A school superintendent presents the evidence he finds of the improvement in the health of school children following upon the adoption of the health program.

HAMMOND, W. E. Checking the Efficiency of a School Health Program. *Pub. Health Nurs.* 24, 11:592 (Nov.), 1932.

Early Indian Health—This story of the health conditions and medical practices among the American aborigines will prove a valuable historical reference. It is significant that the settlers caught no epidemic diseases from the Indians, whereas they gave them plenty.

HRDLICKA, A. Disease, Medicine and Surgery Among the American Aborigines. *J.A.M.A.* 99, 20:1661 (Nov. 12), 1932.

Milk Bottle Caps—Will two caps on a bottle of milk keep out more bacteria than one? The answer is, yes, and 16 pages of argument, tables and graphs are taken to prove it. "Under certain conditions," concludes the paper, "milk in bottles sealed with the ordinary disc type cap may present a definite hazard to health." So another bogey is arising to make us more skeptical about the milk we bring ourselves to drink.

ISAACS, M. L. and ZERBER, I. A Comparative Study of Milk in Bottles with Single and Double Caps. *Am. J. Hyg.* 16, 3:806 (Nov.), 1932.

Testing Adults for Tuberculosis—The technic of a quantitative tuber-

culin test for adults is described. The author claims for it a 90 per cent accuracy equal to that of the routine test applied to children.

KING, R. B. A Tuberculin Test of Value in Adults. *New Eng. J. Med.* 207, 19:831 (Nov. 10), 1932.

Postpartum Care—"The ultimated welfare of the parturient woman cannot be secured by good antepartum and intrapartum care alone, but requires equally good postpartum attention." This conclusion precedes the enumeration of the factors that constitute good after-care of the mother.

LITZENBERGER, J. C. Preventable Invalidism Following Childbirth. *J.A.M.A.* 99, 21:1740 (Nov. 19), 1932.

Harvey's Contribution to Public Health—It seems that we are indebted to Harvey for far more than the demonstration of the circulation of the blood which laid the foundations of physiology and modern preventive medicine, for the movements which his work initiated were the beginning of present-day health administration.

NEWMAN, G. The Debt of Preventive Medicine to Harvey and the College of Physicians. *Lancet* 223, 17:877 (Oct. 22), 1932; *Brit. M. J.* No. 3746 (Oct. 22), 1932.

Bacterial Transformations—To date seven different pathogenic bacteria have been transformed from the visible state to the filter passing stage and back again to the ordinary condition. The practical application of these studies is set forth in this excellent non-technical radio talk on this new but highly important subject. It is well worth reading by health workers.

SIMONDS, J. P. Making Bacteria Invisible and Its Significance. *Sci. Month.*, Dec., 1932, p. 481.

NEWS FROM THE FIELD

PUBLIC HEALTH NURSING CONTEST

THE winner of the first prize in a case story contest conducted by *Public Health Nursing* was Mary H. Emberton, a supervisor on the Visiting Nurse Association staff in Denver. There were 124 manuscripts submitted. The second prize was awarded to Charlotte M. Young, R.N., whose manuscript was submitted by Florence E. McClinchey, of Mount Pleasant, Mich. Edith M. McCarthy, of Medford, Mass., won third prize.

STUDENT HEALTH ASSOCIATION MEETING

THE 13th Annual Meeting of the American Student Health Association was held December 28-29, in New York City, in conjunction with the Society of Directors of Physical Education in Colleges, the American Football Coaches' Association, and the National Collegiate Athletic Association.

WESTERN BRANCH MEETING

THE Western Branch A.P.H.A. meeting will be held in Pasadena, Calif., May 29-31.

NEW JERSEY EDUCATION SURVEY

DR. ROBERT P. FISCHER, Secretary and Chief Chemist of the Board of Pharmacy of the State of New Jersey has been appointed a member of the State Educational Survey Commission. The duties of the Commission are to survey the educational system of the state and to propose recommendations for an essential program of modern education and methods of financing it. The Commission includes the State

Commissioner of Education, a number of school superintendents and principals and a number of prominent laymen, all of whom will serve without pay. Thomas N. McCarter, President of the Public Service Corporation of New Jersey, is the Chairman of the Commission and Albert Payson Terhune, the well-known author, is one of the members.

STANDARDS APPROVED

TWO sets of standards "Essential Features in the Design of Sanitary Drinking Fountains" and "Minimum Qualifications for Those Appointed to Positions in Public Health Nursing" have been formally approved by the Committee on Research and Standards and by the Governing Council of the American Public Health Association. These standards which have already been printed, the first in the *1930 Year Book* and the other in the *American Journal of Public Health*, May, 1931, were prepared by the Committee on Plumbing of the American Public Health Association together with the Conference of State Sanitary Engineers and the Committee on Education of the National Organization for Public Health Nursing respectively.

NEW YORK STATE SEWAGE WORKS ASSOCIATION

THE Fifth Annual Meeting of the New York State Sewage Works Association will be held in New York, January 17. In the evening the association will join the Sanitary Engineering Division of the American Society of Civil Engineers at their annual dinner at the Hotel McAlpin.

THE SIN OF BEING DULL

BEING dull is one of "The Six Deadly Sins," attributed by Guy Holt to those who make and distribute books.

The sin of being dull. That is peculiarly a writer's sin, but it is one which publishers too often encourage. We overlook, I fear, the fact that anything no matter of what moment is lifeless if it be not interestingly presented. We begin in the schools by instilling in our children a hearty distaste for knowledge, when so little imagination could translate almost any subject into a challenge to curiosity. And we carry the deadly tradition on into the field of adult books, and wonder why people, no longer under compulsion to read, prefer ignorance to tedium. Happily this condition is changing. Men eminent in research and scholarship have been found who write dramatically and invitingly of science, of history, even of economics. But the time has not yet come when in every publishing house a book of serious import must pass the two-fold test of accurate scholarship and of interest.—

Publishers' Weekly, New York. Oct. 15, 1932. E. G. R.

PERSONALS

DR. E. R. SHAFFER, F.A.P.H.A., has been appointed Chief of the Bureau of Child Hygiene of the Ohio State Department of Health.

RAY H. EVERETT, F.A.P.H.A., was elected Executive Secretary of the District of Columbia Social Hygiene Society, assuming office on November 15.

MRS. HUGH BRADFORD, of Sacramento, Calif., will represent the National Congress of Parents and Teachers at the World Federation Conference, to be held in Dublin, Ireland, July 29–August 4, 1933.

DR. IRA O. CHURCH, member A.P.H.A., Health Officer of Contra Costa County, Calif., has been appointed assistant medical director of Alameda County under an emergency ordinance recently passed.

DR. FRED P. HELM, formerly of Miami, Okla., has been appointed Health Officer of Topeka, Kans., succeeding Dr. Aurel Goodwin, who resigned.

DR. TILLMAN C. BRITT, member A.P.H.A., of Washington, N. C., has been appointed Health Officer of Surry County, to succeed Dr. Malcolm T. Foster, Mount Airy, on leave of absence.

DEATHS

DR. CALVIN L. COOPER, member A.P.H.A., and Kansas City, Mo., Health Director, died December 1.

EDITH VIVIAN EVANS, Director of the Occupational Therapy Department of the Neurological Institute of New York at the Medical Centre, and President of the New York State Association of Occupational Therapy, died November 27.

Aerial Nuisances from the Refining and Burning of Petroleum Oils*

STEPHEN DEM. GAGE, F.A.P.H.A.

Consulting Sanitary Engineer, Providence, R. I.

THE question of whether pollution of outdoor air by offensive odors should be considered a public health matter has occasioned more or less difference of opinion in the past. Most health officials have inclined to the opinion that while such odors might be offensive and thereby constitute a nuisance, they do not directly cause disease, and therefore cannot be considered as affecting the public health. There is, however, a somewhat different interpretation which may be placed on the terms "health" and "odor." An odor considered purely in its olfactory sense as something which may be smelled, may not cause specific and lasting disease although it may be offensive. Nevertheless, such an odor may be so repulsive to certain persons as to cause reflex action of the nervous and muscular systems leading to digestive and other systemic disturbance which will seriously interfere with regular performance of ordinary duties. Frequently repeated, such disturbances may also readily affect the general health of the individual, causing a lowered vitality and a decreased resistance to disease.

Many substances which affect the olfactory senses are direct poisons, or cause irritation of the mucous surfaces, rendering them more susceptible to infection. On the other hand, certain gaseous substances, such as carbon monoxide, are direct poisons, although they are entirely odorless. The first produce reactions which may be termed psychological, while the others produce a true physiological reaction. There is, however, no sharp line of demarcation between

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

these two classes of reactions nor between the aerial conveyed bodies which produce them. Odors arising from so-called nuisances are frequently made up of a mixture of gases and finely divided particles of solid or liquid matters in suspension, the effect of the odor being the combined effect of its components, which may set up both sets of reactions simultaneously.

The sense of smell and the reaction to different odors or irritants varies widely in different persons. A concentration of odor which might pass unnoticed by the majority might be disagreeable to a considerable number, and extremely offensive and irritating to a comparatively few; yet these few may suffer severely if the visitation of this particular odor is frequent or long continued. Because the olfactory sense in such persons is more highly developed is no reason why they should be termed cranks or neurotics. Public health in a broad sense must include the few as well as the many.

By reducing or eliminating atmospheric pollution by offensive odors we may be building better than we know. In the days when water purification was in its infancy health authorities were much surprised to find that by bringing purified water into typhoid ridden communities not only was the death rate from water-borne disease reduced but there was also a marked falling off in the death rate from other diseases. This effect is known as the Mills-Reinke phenomenon. If such a striking phenomenon followed a clean-up of the public water supplies, may we not expect some similar phenomenon to result from a clean-up of public air supplies. Under such a premise the abatement of offensive odor nuisances and the correction of atmospheric pollution becomes a proper field for extended activity by the public health engineer.

As a rule, cases of atmospheric pollution affect a relatively small area, and the number of people exposed is so small that the real health hazard, if any, cannot be studied to advantage. Perhaps it is for this reason that so little authentic information is available as to the effect on health of the pollution of outdoor air by offensive odors.

THE PROVIDENCE ODOR INVESTIGATION

In Rhode Island the power to abate nuisances is vested entirely in the municipal authorities, and the State Health Department acts only in an advisory capacity, and on the request of local authorities. In 1919, however, complaints that public health was being jeopardized by an odor nuisance in the Providence Metropolitan area became so numerous and so widespread that the General Assembly at its 1920 session ordered an investigation by the State Board of Health. In

this investigation, which was conducted by the writer, we endeavored to cover 3 principal points: (1) The origin of the odors and the cause thereof. (2) The degree of magnitude of the nuisance, that is, the frequency and duration of the odor manifestations, the intensity of the odor at different times and at different places, and the area and population affected. (3) The effect, if any, of the odors upon the health of persons residing in the affected areas.

Interesting as they may be, time does not permit me to discuss the methods and results of this investigation, except in so far as they are related to the public health phase of the problem.

Although it was at first believed that the nuisance was originating from 2 plants, 1 engaged in the refining of crude petroleum and the other in the manufacture of asphalt from petroleum, it developed that odor nuisances affecting the same general territory were originating from at least 4 large oil burning power plants—a gas works, a plant manufacturing road binders and other products from gas tar, a plant manufacturing ammonia from gas liquors, and a slaughter house and rendering establishment. In addition, oil burning installations for heating a number of office buildings and commercial establishments, and a considerable number of private homes were believed to be contributing to the nuisance. In a study of the public health phase of the problem, therefore, we had to take into consideration not only the possible effect of the volatile constituents arising from the breakdown of crude petroleum under distillation, but also the effect of gases, etc., produced by more or less complete combustion of petroleum oils, and the effect of substances given off from the other industrial processes noted.

The total area subject to the effect of these odors was about 23 square miles with a resident population of over 126,000. In one of the 3 districts into which this area was divided for study, an offensive odor nuisance was recorded on 112 of the 158 days this district was under observation. In the other 2 districts, odor nuisances were recorded on 75 out of 121 days, and on 57 out of 148 days respectively.

We attempted to obtain data as to the public health phase of this problem by two methods: By employing a qualified physician, who had had experience in industrial hygiene, to make a special inquiry among persons who claimed their health was being affected by the odors; and by a letter of inquiry, or questionnaire, sent to all practicing physicians in the state, requesting full information as to patients under their care who had apparently been made ill by the odors, or whose illness from other causes was being aggravated by the odors. The physicians were also asked to express their opinion as to the

effect of offensive odors in general, and certain volatile or gaseous substances in particular, upon both normal persons and persons who were suffering from certain diseases.

HEALTH SURVEY IN ODOR AFFECTED AREA

In our direct investigation among the residents of the odor affected districts it was impossible because of lack of funds to make a house-to-house canvass to obtain full and complete statistics. However, it was possible to interview something like 300 different persons, mostly complainants, scattered throughout these districts, and to obtain from them complete data as to the effect of the odors upon various members of their families. This inquiry therefore covered a representative population of about 1,000 to 1,200, among whom were found 89 who were being made ill by the odors, or whose illness from other causes was being aggravated by the odors. To this number may be added 7 additional cases reported by physicians, making a total of 96 cases of which we were able to obtain a complete history. Seventy-five were females and 21 males. It might be stated that in my experience women and children appear to be more susceptible to obnoxious odors than are men. The large preponderance of women in this particular case, however, may have been due in part to the fact that visits were made only in the daytime and a large proportion of the persons interviewed were women.

The most common symptoms complained of were irritation of the throat, suffocation or choking sensation, nausea, headache, dizziness, and malaise. Twenty-four persons stated that the odors would wake them from a sound sleep. Seventy-seven persons exhibited two or more symptoms, 46 gave a history of three or more symptoms, and 14 a history of four or more symptoms.

In a considerable number of cases, those affected would be awakened by a suffocating or choking sensation, which would be followed by nausea. A number of persons complained of a dizziness so marked that they were unable to get up to shut the windows. In quite a large

TABLE I

| <i>Symptom</i> | <i>Number of Persons</i> |
|--------------------------------|--------------------------|
| Nausea | 56 |
| Headache | 44 |
| Irritation of throat | 42 |
| Suffocation | 27 |
| Malaise | 25 |
| Dizziness | 22 |
| Choking sensation | 13 |
| Irritation of nose | 5 |
| Irritation of eyes | 2 |
| Gastric trouble | 2 |

proportion of cases it was stated that the nausea, dizziness, and headache persisted into the following day, many hours after the odors had ceased to be noticeable. The number of persons exhibiting the various symptoms is given in Table I.

OPINIONS OF PHYSICIANS

In the letter inquiry among practicing physicians, about 725 questionnaires were sent out, and 190 replies were received. Ten physicians reported data on 32 patients who were being affected by the odors, 7 of whom had not been picked up in our canvass of complainants. The symptoms reported are shown in Table II.

TABLE II

| <i>Symptom</i> | <i>Number of Persons</i> |
|---|--------------------------|
| Headache, cyanosis, pains in chest and abdomen... | 10 |
| Nausea and vomiting..... | 6 |
| Nausea and malaise..... | 6 |
| Nausea, headache and insomnia..... | 3 |
| Nausea, suffocation and sore throat..... | 3 |
| Headache and suffocation..... | 2 |
| Nausea, headache, insomnia and suffocation..... | 1 |
| Nausea, headache and loss of appetite..... | 1 |

Nine physicians also reported having 15 patients ill with other diseases whose condition was being unfavorably affected by exposure to the odors. The types of cases reported included pulmonary tuberculosis, asthma, pharyngitis, laryngitis, cardiac trouble, and nervous diseases.

The opinions of this group of physicians as to the effect of certain volatile and gaseous constituents probably present in the air of the affected districts is interesting as showing the trend of medical opinion at the time. Between 120 and 150 physicians replied to our various questions relating to this point, the majority of opinions being that air polluted by the volatile constituents of petroleum, by sulphides, or by sulphur dioxide, might affect the health of normal persons, and would certainly affect unfavorably the health of persons suffering from respiratory or nervous diseases or from asthma.

CONCLUSIONS

If we compare the list of symptoms produced in the 96 persons recorded as being made ill by odors with the symptoms which are known to be produced by the volatile and gaseous constituents which escape into the air in the distillation of crude petroleum, or from the stacks of plants using oil as fuel, we find that they are practically identical.

It is well recognized that the vapors and gases from the process of distillation of crude petroleum may produce both acute and chronic symptoms. Benzene, for example, in the proportion of 50 p.p.m. in air is extremely poisonous and in a concentration of 20 p.p.m. produces local symptoms. The still gases from

refineries handling high sulphur oils contain sulphides, either as organic sulphides or as hydrogen sulphide, and also probably carbon bisulphide, all of which are highly poisonous and produce symptomatic disturbances when diluted with considerable volumes of air. During combustion these sulphides are converted to sulphur dioxide and in some cases to sulphur trioxide, both of which affect the respiratory and digestive systems. With incomplete combustion, such as was frequently observed in our study of oil burning plants, carbon monoxide may be given off in considerable quantities.

The chain of circumstantial evidence seems to be complete that the illness of 96 persons was caused by atmospheric pollution arising from destructive distillation of high sulphur petroleum or from the use of such petroleum oils in large quantities for fuel.

Owing to the closure of the Mexican oil fields by revolutionary disturbances, the petroleum brought to Rhode Island for refining and for use as fuel in recent years has been of relatively low sulphur content. While the writer has occasionally noted odors in these formerly odor-ridden districts, their frequency and intensity have been very largely reduced, and complaints from residents have practically ceased. Nevertheless, while the atmospheric pollution by odoriferous and irritating sulphur compounds has been greatly reduced, they must still be present in small amounts, and there can have been no material reduction in the pollution by non-odorous volatile petroleum constituents. It would be interesting if a resurvey of this district could be made to determine whether former complainants had been cured of their ailments, or they had merely stopped complaining because they could not smell the atmospheric pollution which must still exist in greater or less measure.

DISCUSSION

EDWARD WRIGHT

Sanitary Engineer, Massachusetts Department of Public Health, Boston, Mass.

THE discussor has read the paper on "Aerial Nuisance from Refining and Burning of Petroleum Oils" and does not feel competent to discuss intelligently the effect of such odors on the public health. This he feels is a medical, physiological, or psychological problem requiring more the attention of a physician than an engineer. Neither is the writer able to discuss intelligently the interesting question raised by Mr. Gage of a possible application of the principle of the Mills-Reinke phenomenon in connection with the control of industrial odors, but he feels that this is something to be hoped for.

So far as major nuisances are concerned in Massachusetts, however, the statutes link comfort with public health, and the writer has had considerable to do with the determination of the extent of such nuisances and their correction. There is little doubt of the effect of certain offensive industrial odors, at times at least, on the public comfort, and it can perhaps sometimes be shown that offensive industrial odors have an effect upon persons suffering from nervous disorders.

It must be pointed out that the workmen in industrial plants are generally well endowed with health. Probably the fairest way to determine the effect of industrial odors on public health is to study the returns on the cases of respiratory diseases in a community subject to industrial odors and make a comparison with the returns from other industrial communities not subject to offensive odors. The

writer believes that the results of certain industrial odors have more of an effect upon the public comfort than those arising from the pollution of streams, and feels that this problem of the control of industrial odors is much more in the public mind, and is likely to continue so, than is the problem of stream pollution purely from a nuisance standpoint.

Some 13 years ago 3 sizeable oil refineries were established in Massachusetts and engaged in the refining of crude oil obtained largely from Mexican fields. This contained large quantities of sulphur, and the escape of sulphuretted hydrogen during processing was a particularly disturbing factor to the residents in the vicinity. In fact, in one instance the odors were known to affect a considerable portion of the Boston Metropolitan District for a distance of 8 to 10 miles. After many minor remedies were made at a cost of several thousands of dollars, it still appeared impossible to control the situation, and the matter was brought into court resulting in a verdict against the company. The court ordered the company to install numerous additional odor elimination devices, but about this time there was a change in the crude oil market, and the company was reorganized. The crudes were changed to those containing less sulphur, and there has since been little complaint.

The writer also investigated for the Massachusetts Department of Public Health in 1922 another large oil refining establishment. Odor control devices and careful policing resulted in a temporary relief from offensive odors, but nevertheless the matter was brought before the courts, and there is an interesting decision in *Strachan and others vs. Beacon Oil Company* (see 251 Mass. 479). This went through the Supreme Court of Massachusetts with a finding decidedly in favor of the company. The following is quoted from the decision:

" . . . The defendant is engaged in a lawful business in the conduct of which it is found that odors necessarily will escape into the air; but it also appears that the defendant has adopted the most approved methods and devices to control and confine such odors at an expense of many thousands of dollars; it also is further found that such odors would not be unbearable or injurious to the health of normal persons. . . . Whether there is a nuisance in a certain locality depends upon the attendant circumstances including the character of the neighborhood, the acts complained of, and their effect upon the comfort or health of people in general. The district where the defendant's plant is situated has for many years been increasingly devoted to manufacturing purposes; some of the plants were there located many years ago and from some of them odors are thrown off at times which are offensive and disagreeable, but as those discharged by the defendant are not injurious to the lives or health of normal persons, it cannot be held that a nuisance exists in view of the findings of the master to the contrary.

"It is a matter of common knowledge that in thickly settled manufacturing communities, the atmosphere is inevitably impregnated with disagreeable odors and impurities. This is one of the annoyances and inconveniences which every one in such a neighborhood must endure. Mere discomfort caused by such conditions without injury to life or health cannot be ruled as matter of law to constitute a nuisance. Each case must depend upon its own facts and no rule can be formulated which will be applicable to all cases. *Rogers v. Elliott*, 146 Mass. 349. *Downing v. Elliott*, 182 Mass. 28. *Stevens v. Rockport Granite Co.*, supra. . . ."

The area in which this industry is located is one of the most intensively developed industrial districts in New England. Complaints continued to come

in, and the Legislature of 1932 passed a resolve, Chapter 40, providing for an investigation by the Department of Public Health. This resolve is in part as follows:

"Resolved, That the department of public health is hereby authorized and directed to investigate the causes of offensive odors, fumes and gases emanating from industrial processes and other sources in the cities of Everett and Chelsea and to determine the effect, if any, of such odors, fumes and gases upon the public health and comfort. For the purposes of this resolve, said department may enter the premises of any person or corporation in the said territory, shall have access to such records and plans relating to odor elimination devices as are on file in the offices of the various corporations therein, and may employ such engineering and other assistance as may be necessary.

"Said department shall report to the general court its findings and its recommendations, if any, together with drafts of legislation necessary for carrying such recommendations into effect. . . ."

An appropriation of \$5,000 was made and the investigation is now well under way. It is inadvisable, of course, to report at present the results or the determination of the department as to the effect of the odors, if any, upon the public health and comfort, as the work has not been completed. The investigation is to include a study of the reported cases of respiratory diseases.

The district includes a large oil refinery, a large chemical works, gas works, varnish plants, etc. The investigation has shown that sulphur compounds of various kinds originate in certain processes and that one of the particularly offensive odors from the refining of oils is of the mercaptan group, frequently referred to by complainants as an onion or garlic odor.

An adaptation of the Palmer dust apparatus has been used in this investigation as in the earlier ones for the determination of SO_2 in the air.

The investigation has indicated that probably one of the most offensive sources of nuisance to contend with in this region is that due to the disposal of acid sludge which is a result of treating crude gasoline with acid for the removal of impurities. This material after treatment is used for fuel purposes, and it is hoped that the study will show a suitable method of disposal. Another source of odor observed is that due to the disposal of large quantities of liquid wastes containing offensive oily substances, and samples of some of these wastes, even when diluted 1 part in 100 million parts of air by volume in the laboratory, have given off perceptible odors. The life of certain pipe lines used for conveying hot oils, gases, and other substances, in certain processes in these industries is very short, and frequent replacements are required in the pipe lines and valves at intervals of 6 months to a year. In recent years an improvement has been made in these pipes by using steel with a larger chromium content, the material being known to the trade as "Enduro." This investigation has indicated not only the necessity of odor control devices but the careful policing of the industries if the conditions complained of are to be corrected.

This whole matter of the detection and elimination of industrial odors and the effect on health was the subject of a symposium before the American Society of Civil Engineers in 1925 which can be found in their *Transactions*, Vol. 89, 1926, p. 339, and while there have been changes and improvements this symposium is perhaps the most comprehensive of any similar series of papers available.

The Bacteriology of the Intestinal Pathogens*

LEON C. HAVENS, M.D., F.A.P.H.A.

Laboratories of State Board of Health, Montgomery, Ala.

THE isolation and identification of pathogenic bacteria from the intestinal tract is one of the most difficult bacteriological problems which confront a public health laboratory. Their isolation, on the one hand, is attended by many technical pitfalls, and, on the other, the administrative control of this important group of diseases rests largely on the results obtained in the laboratory. Any significant organisms which may be found require intelligent and careful work for their identification. The technical difficulties involved require special training and experience; a thorough knowledge of bacteriological methods and principles is necessary for accurate results. There seems at present no way for the inexperienced worker to acquire this knowledge except through actual experience, and often at the expense of serious error. One is impressed, in studying the available treatises on diagnostic methods, by the casual manner in which the bacteriology of the intestinal infections has been handled. Perhaps the chief reason for this is the very lack of uniformity in methods, and their multiplicity, but the result is that many clinical laboratories, as well as some of the smaller public health laboratories, make little attempt to interest themselves in the practical applications of bacteriologic methods in the diagnosis of this group of infections.

The subject falls into 3 divisions: (1) preservation of the specimen; (2) methods for isolation, and (3) identification of significant organisms. Each of these is important, but the preservation and isolation usually present the greatest difficulties. Many special media have been described, particularly for the isolation of the typhoid group, while the preservation of feces for bacteriological study has not received the attention which it seems to deserve. Almost every bacteriologist has his favorite procedures which are more or less successful in his own hands; consequently, he hesitates to accept new methods or modifications of old ones.

* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

Even when the isolation procedures can be started promptly with the freshly-passed stool, some means of preserving the specimen for further study are desirable, because it has been our experience that repeated platings materially increase the number of positive results. In most public health laboratories considerable time is bound to elapse between the collection of the specimen and its arrival at the laboratory, and this delay makes some good preservative medium the first essential of a reliable examination.

After one is assured of a properly preserved specimen, the successful isolation of any pathogen which may be present is determined not only by the media used but also by the care with which the plates are streaked. The well-nigh universal practice of permitting this important step to rest upon a single plate or series of plates prepared at the same time is comparable to reporting a blood culture negative after only 24 hours' incubation. A good preservative medium permits survival of *B. typhosus* and related organisms for several days, with a progressive diminution of the fecal flora. When the original number of typhoid bacilli is small, colonies will frequently appear on plates streaked the second or third day, after further decrease of the fecal bacteria has occurred.

Furthermore, a plating medium which has a sharp selective action will permit the development of typhoid colonies, when another, which is less effective in inhibiting the colon group, will give entirely negative results. Our own observations indicate that *B. typhosus* survives a long time in feces; it is not so much its early death which causes negative results as the enormous overgrowth of *B. coli* which prevents the appearance of the typhoid colonies on the plates.

The identification of members of the typhoid-paratyphoid group, in the hands of competent bacteriologists, usually offers no difficulties. Dissociative changes may sometimes make a particular strain atypical in certain respects, but the sum total of a thorough cultural study, together with the serological reactions, usually makes the identification certain. There should surely be no excuse for confusing *B. proteus* with *B. typhosus*, nor should a strain of *B. coli* merely because it happens to ferment lactose slowly, be mistaken for a dysentery bacillus. Everyone who has had extended experience with fecal bacteriology, has found numerous unclassifiable bacteria which sufficiently resemble the established pathogenic types to cause at least momentary confusion. Some of these differ culturally only in their reaction on a single carbohydrate; but, serologically, they cannot be brought into relationship with any known species. On the other hand, some strains show such overlapping, both in cultural and serologic characteristics

as to make classification difficult, if not impossible. Whether these organisms are variants of known types, and whether they are even pathogenic, there is no evidence on which to base an opinion, but their chief bacteriological importance seems to lie in their confusing resemblance to known pathogens, with the consequent necessity for their differentiation in arriving at the etiologic agent in any given case.

In addition to these technical phases of the subject there are field problems of prime importance to a thorough and intelligent understanding of the mode of spread of the enteric diseases. The significance of the healthy carrier in the causation of outbreaks, the geographic distribution of carriers, the relation of subclinical infections to the carrier condition, are questions which require close coöperation between the epidemiologist and the bacteriologist for the most effective solution. The antigenic relationships in the dysentery and Salmonella groups and the practical significance of the different antigenic components of these bacteria are other problems which await additional knowledge before their full epidemiologic applications can be intelligently evaluated.

Public health laboratories are depended upon for by far the larger portion of intestinal bacteriology. Carrier surveys must often be made on an extensive scale, and convalescent cultures must be dependable. Upon the results of the laboratory rests the effective control of the enteric infections. I know of no service which the Committee on Standard Methods of this section could render which would be of more value, particularly to the small laboratory, than to create some degree of order out of the technical chaos which now exists. It is essential that the results of official laboratories be comparable. The need, therefore, for special study of bacteriologic procedure, and group judgment as to the best methods for official examinations, especially of typhoid carriers and convalescent cultures, is urgent.

This is not the place to discuss technical details, but it seems to me that a study of the various phases of the subject could do much to clarify the situation, even if full agreement were not reached with regard to all procedures. The thorough-going investigation of complement fixation in syphilis which Dr. Ruth Gilbert has made as referee for the committee, while it has not evolved a technic which is acceptable in every detail to all laboratories, did serve a very important purpose in emphasizing some of the current technical faults, and undoubtedly resulted in a general improvement in methods and results.

A similar approach might be made to the subject of the intestinal pathogens. Criteria could be established for minimum acceptability which would probably receive practically universal agreement by the

larger laboratories and be very helpful to smaller ones which are handicapped by lack of extensive material on which to base their judgments and interpretations.

These minimum requirements, it seems to me, should include general specifications for satisfactory preservative media, the use of selective media for isolation and acceptable procedures for identification, including the essentials for classification, both cultural and serological. Reasonable standards covering these phases of technic should meet little difficulty in gaining acceptance and should increase the effectiveness of many laboratories in this particular field.

Anthony van Leeuwenhoek

THE year 1932 was the 300th anniversary of the birth of Van Leeuwenhoek. Although a drygoods merchant devoid of medical training, he became interested in facts concerning the body, and made a communication to the Royal Society of London in 1673 concerning the blood, in which he states that he had oftentimes wondered of what parts it consisted. Finally he took blood out of his own hand and found "small, round globuls driven through a Crystalline humidity or water." He doubted that all blood was like this and noticed that in the small amounts examined, color was practically absent. This communication is said "to have shaken that august body to its foundations."

We remember him, however, chiefly on account of his improvement in the microscope. Up to his time, the highest magnification had been from 25 to 30 times, while van Leeuwenhoek was able to increase this to from 80 to 270 times. He is said to have owned 247 microscopes and 419 lenses, most of which he ground himself. He was the first to describe spermatozoa; he discovered the striations in voluntary muscle; the structure of the crystalline lens; demonstrated anew the capillary anastomoses between arteries and veins; described what is called animalculae in water in 1675; found microorganisms about the teeth, and was the first to draw bacterial chains, clumps, rods and spirilla. One of his communications was made to the Philosophical Society of London in 1675. He was elected F.R.S.

His death took place in 1723 at the age of 91. He is buried in the Old Church at Delft, and the epitaph on his monument ends with the following words: "As everybody, O Wanderer, has respect for old age and wonderful parts, tread this spot with respect; here grey science lies buried with Leeuwenhoek."—Abstract, *Canad. M. A. J.*, Nov., 1932.

Maternal Mortality Study for Cleveland, Ohio*

RICHARD A. BOLT, M.D., DR.P.H., F.A.P.H.A.

Director of Cleveland Child Health Association, Cleveland, O.

A COMPLETE and detailed study has been attempted of every puerperal death occurring within the confines of the City of Cleveland during 1931. This includes the deaths of women from all causes dependent more or less directly upon pregnancy at any stage of gestation and upon parturition. It requires a careful scrutiny of every death recorded as puerperal by the local Bureau of Vital Statistics of the City Division of Health. It includes so-called "Criminal Abortions," which are usually classified as homicides. These are as truly puerperal as those following self-induced or therapeutic abortions, and they should be included in any complete study of puerperal mortality. Every coroner's case involving the puerperal state has been investigated thoroughly. The deaths of all females between the ages of 15 and 50 years also have been checked against the live births and stillbirths. Every association between them, suggested by similarity of name, place of residence or of birth, and time of birth, has been followed up to determine possible puerperal relationships. The official number of puerperal deaths in Cleveland during 1931 was 117. This study revealed 151 puerperal deaths, including the 12 criminal abortions, which could be so classified.

Basic data in addition have been secured from individual physicians, midwives, hospital records, and the Visiting Nurse Association. The items have been recorded on schedules prepared by an advisory committee of the U. S. Children's Bureau. They have been analyzed in the office of the Cleveland Child Health Association. This study was undertaken with the approval of the Academy of Medicine of Cleveland and was made possible by the thorough coöperation of the Cleveland Division of Health, individual physicians, maternity and general hospitals, coroner's office, and the Visiting Nurse Association.

* Summary of paper read before the Child Hygiene Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932. The complete paper with tables and charts will be published elsewhere.

During 1931 there were 16,279 live births and 592 stillbirths. Of those born alive, 496 died under 2 weeks of age and 527 under 1 month. There were 151 puerperal deaths, giving a puerperal mortality rate of 9.3 per 1,000 live births or 8.9 per 1,000 live births and stillbirths. The official puerperal mortality rate based upon 117 recorded deaths was 7.2 per 1,000 live births.

It is highly desirable that a distinction be made between viable births, which may be expected to survive, and those which have little possibility of living. In this study there were puerperal deaths following 50 abortions, 8 ruptured ectopics, and 7 undelivered, all under 28 weeks of uterogestation, and 2 undelivered over 28 weeks. This leaves only 84 viable births. A maternal mortality rate based on this number would be 5.2 per 1,000 live births. Thus it is seen that after removing all abortion deaths there remains a fairly high maternal mortality rate.

In this study every fetus under 28 weeks of gestation is considered as non-viable and its premature expulsion is classified as an abortion. Of the 50 puerperal deaths following abortion 16 were spontaneous, 14 self-induced, 12 criminal, 6 therapeutic, and 2 of unknown origin. The primary causes of death following these abortions were sepsis alone in 35 cases, hemorrhage alone in 7, sepsis with hemorrhage in 2, and 1 case each of embolism, lung abscess, myocarditis, toxemia, intestinal obstruction, and pulmonary tuberculosis. Abortions, therefore, make up one-third of the total puerperal deaths. In over 70 per cent of these abortions sepsis was the primary cause of death. In 42 of the abortion cases there was no prenatal care, in 5 the care was inadequate, and in only 3 could it be considered adequate. Following 31 of the abortions some operative procedures were instituted. In very few of the abortions was it possible to secure any prenatal care. It is misleading, therefore, to make any comparison of maternal mortality in the community at large, where all deaths from abortions are included, with the mortality among maternity cases under intensive care after the middle of pregnancy.

Abortion undoubtedly has been on the increase since the World War. This condition may be one of the main factors in the stationary or increasing puerperal mortality rates in this country. It can be shown from other data that it is fallacious to compare maternal mortality rates in the United States with those in other countries, where definition of terms, methods of classification, and interpretation of records differ widely. Even in the Cleveland study 33 puerperal deaths of the 151 were subject to diagnoses or interpretations different from those recorded in the original death certificates.

Of the 1,679 registered physicians in Cleveland, 853 attended one or more of 16,005 live and stillbirths during 1931, or 95 per cent of the total births. About one-sixth of the physicians had over 20 confinements. The majority had 5 or less during the year; 80 physicians listed as obstetricians and gynecologists attended approximately 34 per cent of the births, 773 general practitioners 61 per cent, and midwives 5 per cent. Nine osteopaths handled 27 obstetrical cases during 1931.

The 151 puerperal deaths occurred in the practice of 109 physicians and 9 midwives. Fifty-five of these occurred in the practice of 33 physicians listed as obstetricians and gynecologists, 87 in the practice of 76 general practitioners, and 9 in the hands of 9 midwives. In other words, 36 per cent of the maternal deaths were handled by specialists, 58 per cent by general practitioners, and 6 per cent by midwives.

Approximately 60 per cent of the total live and stillbirths (10,115 confinements) occurred in 31 hospitals; 85 per cent of the puerperal deaths occurred in these same hospitals. The maternal mortality rates varied greatly depending upon the nature of the hospital, composition of staff, and selection of cases. The exclusively maternity hospitals showed the lowest rates (combined rate 5.9 per 1,000 live births) as contrasted with the general hospitals with maternity licenses (rate 14.4). If comparison be made on the basis of viable births only the rates in the maternity and general hospitals closely approach one another. The city hospital, however, to which all types of cases are referred, had an exceptionally high mortality. The puerperal mortality rate for the 6,756 home cases was 3.5 per 1,000 live births as compared with 13.1 in the hospitals as a whole. It should be noted, however, that practically all the deaths following abortion and many of the complicated deliveries occurred in the hospitals. However, if all abortion deaths are eliminated, the hospital rate still remains considerably higher than that in the homes.

There were 98 registered midwives in Cleveland in 1931. Of these 87 attended 811 live births and 9 stillbirths. Nine puerperal deaths occurred among cases with which the midwife had anything to do. Every puerperal death in which a midwife contact could be traced was credited to the midwife and not to the doctor signing the death certificate. Five of the 9 puerperal deaths followed criminal abortions induced by midwives and later turned over to physicians. All of these died of sepsis. One midwife's case with a difficult impacted shoulder was delivered by a physician and died of sepsis. Three deaths occurred suddenly, apparently from emboli, on the 3rd, 8th, and 36th

day after normal deliveries. If we exclude the abortion deaths, we find that the puerperal mortality rate among viable cases in midwives' practice (5.0) is still lower than that among physicians' cases (6.3 per 1,000 live births).

The primary causes of death among the 84 women giving birth to viable fetuses were as follows: puerperal septicemia 19; various accidents of labor including cesarean section, instrumentation, surgical interference, version, etc., 18; toxemias of pregnancy 12; puerperal hemorrhage 8; emboli 8; other accidents of pregnancy 6; lobar pneumonia 4; pulmonary tuberculosis 2; puerperal psychosis 2; and 1 death each from scarlet fever, influenza, cerebrospinal meningitis, chronic nephritis, and anesthetic shock. One of the undelivered cases died of bronchopneumonia, and the other was an anesthetic death.

As contributing or secondary causes, accidents of labor took first place with 21 cases, pneumonia came second with 15 cases, and diseases of the heart third with 14 cases. It is seen, therefore, that while a number of different conditions may play a secondary or contributing part, the puerperal state itself was mainly responsible for the deaths, with sepsis as the leading cause and accidents of labor and toxemias as close seconds.

There were 12 deaths following classical cesarean section, and 4 following cervical section. Eight deaths followed internal podalic version and extraction, and 7 followed breech extraction. The number of deaths, following forceps delivery were as follows: "prophylactic forceps" 4, low forceps 16, mid-forceps 3, and high forceps 1, a total of 24 forceps deliveries. In 28 cases only were the deliveries spontaneous.

Other analyses from the basic data will bring out factors relating to age distribution and parity, length of time attended by physician, adequacy of prenatal care, birthplace, marital status, and occupation. It also will be possible, with the aid of data assembled by Howard Whipple Green, to indicate distribution of births, puerperal deaths, stillbirths, and deaths under 1 month, in economic areas comprised of census tracts having equivalent monthly rental values.

CONCLUSIONS

1. Factors entering into puerperal mortality are so interwoven with the social, economic, and cultural fabric of the community that it is impossible to evaluate them without a detailed study of each individual case.

2. Comparison of maternal mortality rates for different communities is misleading unless definition of terms, methods of collecting data, and interpretation of records are comparable.

3. Deaths following abortion should be separated from deaths after the 28th week of uterogestation to gain a true picture of the situation.

4. The midwife, aside from abortions, plays a relatively minor rôle in contributing to the high maternal mortality rate.

5. Sepsis, toxemias and hemorrhage play the major tragic rôles, and these are associated largely with hurried, operative, and bizarre obstetrics.

6. Prenatal care and hospitalization are accessories to the actual obstetric situation. They may or may not be associated with a low maternal mortality, depending upon the type of medical, nursing, and hospital care afforded.

7. Not every maternal death is, at present, preventable. Fundamental changes must take place in the socio-economic order and more complete medical knowledge and skill be available in order to approach this ideal.

Bovine Tuberculosis

JENSEN asks, "Is bovine infection in man so extensive and the cause of so much serious disease that more effective measures against it than those already in force are needed?"

For 9 years he has isolated and typed tubercle bacilli from various tuberculous lesions. Some 400 cultures have been studied with the following results: 37 cases of pleural effusion, 36 bovine, 1 human; urino-genital, 16 cases, 13 human, 3 bovine; cerebrospinal fluid, ratio of human to the bovine type, 34 to 11; cervical glands, 23 cases human, 31 bovine. Other forms of surgical tuberculosis, 68 human, 5 bovine. He finds that tuberculosis of the glands of the neck traceable to the bovine type is at least as frequent as the human in Copenhagen as in the provinces. He answers his own question emphatically in the affirmative.—Abstr. by C. Lillingston in *Bull. Hyg.*, Nov., 1932, p. 710.

Motivation in Health Education*

BENJAMIN C. GRUENBERG

New York, N. Y.

HEALTH education we may take to mean the sum of all efforts to modify human conduct and attitudes so as to raise the health level of individuals or of the community. It includes the education of the diabetic or of the tuberculous in his personal regimen, propaganda for immunizing children against diphtheria or smallpox, and the promotion of sales of cod liver oil or tooth pastes. In such education the most frequent appeal in the past has been to fear. If you eat green apples you will get the gripes. If you don't brush your teeth the goblins will get you. Horrible pictures of smallpox victims, horrible statistics of deaths from preventable diseases, horrible reminders of aches and pains, horrible portraits of rickety children—horrible devices of various sorts to arouse horror.

We could make out a good case for the appeal to fear on strictly logical grounds. We can still hear the reverberating echoes of the solemn dictum that "self-preservation is the first law of nature," even if we are not exactly clear as to what it means; and with that first law as a major premise we can rationalize taking the easier way of trying to scare people into being healthy. But that would hardly be a demonstration of the effectiveness of the technic. Of course, people are influenced by fear; of course a burned child dreads the fire; but we still have to answer the question—How can we most effectively influence people's conduct in the direction of maintaining or of improving their health?

To demonstrate the effectiveness of the appeal to fear we can point to the thousands who no longer shake the hands of those they meet, who never kiss those they love, who polish the tableware in hotels and restaurants with their napkins, and who shield their babies not only from the evil eye but from the false lips of lady friends and politicians. We can also point to the entire armies that boil all the water they take internally, as well as to entire counties or larger governmental units in which the inhabitants always close their windows at night to avoid malaria—a practice which is said to account for the salubrious atmos-

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

phere of country districts. Granting that the various practices and avoidances are desirable in the interests of health, it is still questionable whether they can be best established at the risk of cultivating phobias and hypochondrias. We can learn to sterilize water or wipe our soup-spoons in public places as standard practice without encouraging the imagination to dwell upon the frightful possibilities of neglect; just as we can establish routine vaccinations and routine Wassermanns without making the flesh creep.

A state of panic is itself undesirable, from a health point of view. Moreover, it interferes with our purposes when considerations of health demand the doing of something rather than the avoidance of dangers—as for example, taking exercise, maintaining erect posture, breathing deeply, chewing thoroughly. We may learn from the manufacturers of soaps and antiseptics and tooth brushes, who have at stake large capital investments and other overhead expenses, and who presumably are searching for the most economical uses of their advertising appropriations—these people have been redirecting the attention of their prospects from the danger of losing teeth or of having them ache, to the satisfactions of handsome teeth or lasting teeth, for example. They have shifted the emphasis from the fear of repelling potential admirers of the opposite sex through body odors or foul breath to the satisfaction that may ensue from making oneself attractive.

It is perhaps significant that when the reliance upon fear in health education was questioned or criticised, the only positive motivations that we could think of were those related to competitive self-aggrandizement. For many years the only alternative to the horrible examples offered young people as inducements to sobriety were in the form of keeping fit campaigns; and keeping fit was commonly glorified as the sure and only means of excelling others in athletic contests.

The solemn inculcation of good rules of conduct designed to maintain health still proceeds over large areas on the assumption that the one grand goal of youthful aspiration is the urge to run faster, jump higher, hit harder, or sit tighter—as in a tug-of-war—than the other fellow. This is supplemented frequently with appealing pictures of two-fisted he-men and, for the girls, pictures of champion golf or tennis players, hurdle riders and channel swimmers. It is only the stupid boys and girls who fail to grasp the connection between observing the rules of health and winning championships. Now while the establishment of this connection in the minds and hearts of young people is not only legitimate but highly desirable, we have to realize (1) that many of these young people do not care in the slightest degree for the

prowess or distinction of athletic achievement; and (2) that most of those who do care can never attain to championship status and therefore are either going to be discouraged and disillusioned by their failure to reap the promised benefits of their efforts and sacrifices, or, being wise enough to see the catch early, are going to avoid the disappointments by dismissing the contest in advance. There is the need, in other words, of recognizing the fallacy of promising, as an inducement to adopt our health programs, either what our prospects do not want, or what we cannot deliver.

On the other hand, keeping fit has values that are unrelated to the competitive strivings, whether in athletics or business. It is worth while for the man or woman of independent means, and for the solitary genius, to be in good health, although these individuals never come into competition with anybody, although they are without care for achieving "more" of anything, although they do not seek to advance themselves. It is worth while to be well, to make some effort toward attaining health, regardless of the particular rivals that have been introduced to stimulate us—health is a factor in the pursuit of any purpose. It is the fact that human beings have such purposes, that they do set themselves goals, which supplies the motivation, not the fact that in many of the relationships we find ourselves adopting competitive attitudes. People want to be effective: sleep has some bearing on one's effectiveness; elimination of refuse from the tissues and from the body has some bearing on one's effectiveness; a steady hand has some bearing on one's effectiveness. Health is of value in play as well as in work, in the contemplative life as well as in the life of action, in the solitary strivings as well as in the joint struggles against others. But again it becomes unnecessary so to emphasize the various health measures that the rituals and practices obscure their purpose: it is not necessary or desirable to make the pursuit of health a major objective of life.

That there is danger of doing just this appears when parents and teachers and physicians put a premium upon eating spinach or breathing through the nose: There must be something deep and mystical about these performances to make adults so awfully solemn. A little boy whose parents had impressed him with the utter goodness of George Washington, with his perfect compliance with all that is right and proper, startled his mother one day by asking, after a period of silent meditation, "Mums, did George Washington have good bowel movement?"

It is not rare for parents to pay children for being "good," for saying their prayers, for taking the afternoon nap, for gulping the cod

liver oil. Perhaps it is not fair to blame the parents for using the easiest way to get done what we have assured them it is well to get done: but while these procedures teach their lessons, we can hardly consider them as sound parts of health education. They are instead part of the confusion of values which does so much to break down health—mental health. A little girl who had been treated for enuresis by means of graded rewards succeeded in increasing her control satisfactorily. After several months had passed, she was again brought to the clinic because of a serious regression. The doctor asked the child what the trouble was. She replied very simply and directly that she needed a certain doll which she had seen in a shop window.

Paying a child a nickel for taking his nap may be effective, just as paying him a nickel for jumping out of bed promptly may be effective, in insuring the desired conduct. However, it is not health education; it is no more health education than is rewarding care of the teeth with candy or penalizing refusal to take cod liver oil by confinement in the dark. Such procedures establish merely a technic of buying and selling, with a corresponding scale of exchange values—a scale and a technic that do not promote health, that rather injure health.

A questionable use of irrelevant inducements to comply with prescribed usage for the sake of health may be seen in the awarding of lollypops and buttons and laudations in connection with a diphtheria immunization campaign. A community which uses lollypops to induce children to come to the clinic can probably get a higher percentage of attendance than one which uses merely a newspaper announcement that the clinic will be held. A clinic which rewards each child with a star for accepting the prick of the needle will perhaps show a larger percentage of submissions than one which overlooks each child in the line beyond applying the needle, or which merely pats his head and murmurs, "That's a fine boy!"—or "girl," as the case may be.

Undoubtedly the physiological effects of the immunization procedure are uninfluenced by the methods used for inducing the children to come and to submit. There may be by-products, however, that also have significance for the health of the community. There is, for example, the potential snobbery of the star-bearers toward the untouchables. There is further the potential inferiority and envy and resentment of the children who, for whatever reason, fail to be gathered into the charmed circle of the elect. A promising research problem would be to follow up a successful sales campaign of this kind with an inquiry as to the number of anti-vaccinationists produced by the establishment among children of invidious distinctions between those who did and those who did not. Urging people to buy what they do

not know they want may make some of them at least refuse to get what they really need.

There is, nevertheless, an economic aspect to the preservation of health and to the practices designed to further health. Illness, aside from pain or suffering, means loss of time; it means reduced efficiency and poorer workmanship; it means burdening the budget with enforced payments for drugs, doctors, and hospitals, and incidental expenses that are seldom met with relish. Even without illness, lowered physical or mental tone, lowered endurance, flabby performance, and high fatigability are substantial handicaps in the economic life as well as in the enjoyment of life, regardless of competitive pressures. Moreover, there is substantial economy in the prevention of illness and in the maintenance of health, as against curing illness. There is economy in overhauling and anticipating, in prompt attention to irregularities that do appear, as against holding out until forced to quit. Such things people can understand and appreciate and act upon, even children, without demanding a premium for looking after their recognized interests.

A more subtle source of motivation in health education, and one that we have not used as extensively and fully as we might, is just the reverse of our common appeals. Instead of assuming that Old Devil Selfishness is the most powerful drive among the children of Adam, we might consider the fact that there is something inside these children that makes them gregarious, not to say social. They care enough about the companionship of others to make substantial sacrifices in the form of curbing impulses. They learn to count ten before striking, to bite their tongues, to wait for the cake to be passed instead of reaching over. In the same way they learn to bathe, to paint their cheeks, whether from the inside or from the outside, to dance and swim, to play tennis and skate, and to do dozens of other more or less artificial stunts for the sake of getting and holding the attention and esteem of their fellows; they discover, that is, that it pays to be healthy, it pays to observe the rules of health, on purely social grounds. Incidentally, too, the same rules have value in a specialized area of social adjustment, for the children of man are sexual as well as vegetative and social.

Still more subtle apparently, since it is so largely overlooked, is the fact that human beings really do care about others. Mothers, for example, do care about their children in the vast majority of cases—so much so that they have been known to sacrifice their own comfort, their own convenience, their own health, for the health of said children. That is, mothers are eager to keep their children well, or to make them

well in case of illness. They do indeed resist the teachings of doctors and nurses and dentists. They do misapply such health education as comes to them. They do neglect important details; but their hearts are still in the right place. It is not necessary to resort to special inducements to improve their technic. They will not do measurably better if we offer them a silver spoon with each bottle of cod liver oil, or a ticket to the movies with each recovery from whooping cough, or the privilege of seeing their names in the social column if they get rid of the mosquito breeding opportunities on their home premises, or of nits on their children's heads. The mothers, generally speaking, want to do what is suitable under the circumstances, for the sake of their children's health. The need is not so much for better motivation on their part as for suitable motivation on the part of doctors and nurses and teachers—motivation to get at the mentality and the prejudices and difficulties of the parents in question.

Similarly, I feel that we could accomplish more in health education if we recognized that young people care about others. There is a real appeal possible to the responsibility which each can be made to feel for the well-being of the community. Instead of saying to the young fellows, "Sleep nine hours and lick the Hoxey team," we might say, "See that the folks in your home, in your town, get a chance to sleep properly and make a happier home or town." That sounds rather cold, but there is something there we have not been using. Many of the young fellows, at least, would rather have a short life and a merry one; that is, they would rather continue to have a good time their own way than modify their program, sacrifice their good time, on the promise of having more time. I submit, in other words, that for healthy young folks health is no object. They are willing to sleep more if that will help the team, but they are equally willing to go without sleep if that will help anybody. They are ready to engage in most unwholesome occupations and risk their necks, just for the adventure; but they are equally willing to engage in such unwholesome occupations for the sake of other people's health—war for example, or epidemiology, or bacteriology.

Young women too can be interested in health matters quite as effectively by appealing to their desire to be of service as by appealing to their vanity, or the desire to stand higher in the history class, or in an athletic contest. The girl is often more eager to learn about suitable diet and regimen for her younger brothers and sisters than to improve her own practices for the furtherance of her own health. Health is no object; but the prevention of suffering on the part of others may well be. Moreover, there is not merely the sympathy and

considerateness of others that may be made effective in health education, but the growing sense of responsibility for the welfare of others, of the whole community.

Much of our effort fails to produce proportionate results because we assume too great a uniformity (1) as to human motivations; and (2) as to desirable objectives.

It is necessary to accept the fact of individual variation not merely in the physical traits that are measurable, but also in the interests, the concerns, and the desires of men and women. We must therefore take into account the dispositions and goals and purposes of people when making our attempts to influence them. We cannot proceed as though one set of motives could be generally relied upon to produce results. We have to differentiate our work according to age and sex, perhaps according to social and geographical areas, or to cultural background, according to occupational interest or place in the family. For young children it is sufficient to establish standard practice. The chief difficulty here is not that of making people accept our rules and doctrines; it is the fact that rules have to be changed with the increase of knowledge, whereas good indoctrination obstructs further learning. At one time protection against night air was sound teaching; or terminal disinfection; or the avoidance of water with meals, or of ice in water. For young and untrained people the solution is to be found probably not in confusing our teaching with excessive qualifications, but (a) in establishing practices with a minimum of preaching; and (b) in a continuity of guidance and reorientation.

With younger children and untrained adults, there will arise resistance to our efforts to modify habits, or overcome inertia, or inhibit impulses, thwart desires. Here we have to rationalize our recommendations as contributions to their health or well-being. With older children and with adults generally, our recommendations have to be rationalized as resting upon experience, or upon scientific research, or upon statistical generalizations. What good does it do a healthy person to get a medical examination? What good does it do a sick person to have his case recorded with the board of health? What good does it do a dead person to have the cause of his death reported? These questions cannot be answered in the terms assumed; health education has to recognize in each case that there are significant categories beyond the individual under consideration; and it has to proceed on the assumption that the individuals are both (a) able to appreciate these other categories, and (b) disposed to be concerned with them.

As to objectives, we know that we cannot promote health in the abstract. Although we look upon the organism as a unity, although

we think of health as somehow related to wholeness, our efforts are directed toward concrete and specific objectives—diet and air, sunlight and water, elimination and cleanliness, exercise and rest, and so on. We set up standards as to nutritive conditions, musculature, skills, controls, endurance. We then call upon each individual to come up and match himself against these abstract norms, or against selected models of perfection. Now this is essentially unwholesome. It calls for comparisons, and comparisons are odious because they are invidious. They invite people to take pride in the gratuitous gifts of the gods, which is humiliating to any self respecting individual; and they demand of people a mortification for things beyond their control, which must arouse the resentment of any self respecting individual. As those whom we urge thus to attempt the impossible become aware of the futility of aspiring to the 100 per cent score, they become indifferent or even hostile.

In many cases too the individual must resist all efforts to relieve him of his health handicap or disadvantage, for the handicap may be one of his chief assets. One's "abnormality" may serve as the principal source of attention and consideration, not merely for exploitation in the sideshow of the circus, but in the daily relation with others. Flat feet will save one from being the family fetch-and-carry. Susan is so nervous, she has to be spared at every turn. The weak heart, whatever that may mean, may be worth two strong ones. People will hug their defects, for these serve often as powerful weapons in their conflicts with the so-called "normal."

Since most individuals have various sorts of aberrations, in more or less serious degree, it may turn out that our health education can be more profitably based upon a program for attaining optimum general well-being than upon the hope of having all individuals attain the maximum. That means for the individual such help as we can muster toward adapting him to live with his troubles and deficiencies—with himself, in short, for people have to live with themselves even if they retire to the wilderness or take a trip around the world: mechanical appliances for a short leg, spectacles for refractive aberrations, insulin or specialized diet, a change of residence from seashore to mountain or *vice versa*, a change of occupation for some, perhaps even a change of religion or of the spouse. It means an education in the acceptance of the unavoidable and the irremediable, without repining, without self reproach, but also without supine submission to all ills, without futile misdirection of our protests and defiances. And, for all of us, it means increasingly an appeal to group consciousness and group responsibilities, as against an appeal to individual advantage.

Although it is always the individual who is sick or well, hygiene as a form of thought, as a technic, or as an effort toward health, is essentially social.

The educator is usually concerned with all the people rather than with this one or that. The individual starts out perhaps concerned only with himself; but through advancing maturity he sees his own health so intimately tied up with that of his fellows that he finds it more economical and more effective to concern himself increasingly with the community or social activities, content to share in the common gains. In so far, at any rate, as those engaged in health education and those exposed to it have common purposes, they will reënforce each other through their efforts. It is part of the technic of health education to recognize and to utilize the motivations of the public at large. It is part of the aim of health education to get more and more of the public—in schools, in homes, in industry, in government—to adopt the motivations of those engaged in health education.

Deaths from Silicosis in Great Britain

A MEMORANDUM recently published by the Home Office gives some interesting facts as to the prevalence of silicosis in Great Britain. The frequency of this disease during the last 3 years is shown in the following table:

| <i>Industry</i> | <i>Number of cases</i> | <i>Deaths</i> |
|--|----------------------------|---------------|
| Ganister mines and silica brick works | 80 | 30 |
| Extraction and manipulation of sandstone | 179 | 25 |
| Pottery industry | 322 | 87 |
| Metal industry (including metal grinding and sandblasting) | 81 | 32 |
| Coal mines | 91 | 20 |
| Total | 753 | 194 |

Investigations are being made by the Department of Scientific and Industrial Research into the efficiency of various types of respirators. Considerable progress has been made, and it is hoped that before long a respirator possessing the necessary properties will be produced.—*Ind. & Lab. Inform.*, XLIV, 1:23 (Oct. 3), 1932. E. R. H.

The Psychology of Public Education*

EDWARD S. ROBINSON

Professor of Psychology, Yale University, New Haven, Conn.

MY proposal is that we need to face the problem of public intelligence in the same humble spirit in which the man of science faces other complex realms of natural fact. We need not make a mystery of the public mind. We need not overlook such solid information as we actually possess. But we do need to give up overconfidence. You who have the urgent and practical need to make widespread education effective in matters of health may feel that this plea for an attitude of honest ignorance is a council of despair, but I do not intend it as such. I mean merely to indicate my distrust in the rules and tricks of public appeal which you may obtain for the asking from many confident publicists.

Consider the course of events in the production of a modern motor car. The designer makes use of all available principles of engineering, but when the paper work is done, it is looked upon in the industry as merely a preliminary step. No manufacturer would think of putting that car into production simply because the design looked plausible. Almost every element in the complex machine is sent to the laboratory.

Those of you who are familiar with the slap-dash manner in which the average campaign of public education is put forth must be struck by the contrast between that method and the one followed by the manufacturer of motor cars. The automobile is based upon the most dependable of all the sciences—the science of physics—yet experience has shown that no amount of theoretic knowledge can circumvent the necessity of empirical test. Campaigns of public education, on the other hand, are based upon social psychology, the theory of which is faltering and the principles of which are vague. Should we not expect an even greater need for feeling our way by means of the most careful checks and experiments?

In 1925 I began to study the behavior of the museum visitor in the hope of showing museum curators that they could not expect, on the

* Read before the Public Health Education Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

basis of theory alone, to reach their public in the most effective manner. Two years later I was approached by a museum director who asked me what kind of labels to use in the new building into which his institution was moving. There were a few direct suggestions which any psychologist could make under the circumstances, but my principal answer was that I could show him and his assistants how to test their own ideas of labelling by means of experiments. This proposal was received politely, but I was not requested to go further with the matter. This experience brought home to me the resistance to the experimental method that is to be expected whenever the problems to be dealt with involve human nature rather than the operation of machines. The more human the problem, the more impatient we are with the arduous exercise of the experimental method.

A short time ago the Psychological Corporation made a study of ideas that were being used in national advertising campaigns. Two thousand housewives were asked such questions as these: What refrigerator is *Dual Automatic*? What toothpaste advertises *Pink Toothbrush*? What company selling canned fruit advertises *Just the Center Slices*? What company advertises *I Smell Smoke*?

To quote from Dr. Henry C. Link: "The correct answers are as low as 20 per cent, 30 per cent, and 40 per cent of the total number of housewives asked in regard to certain campaigns, and as high as 50 per cent and even 75 per cent in other cases." When the amount spent in advertising was considered, one slogan was found to be 150 times as effective as another.

Now the astonishing fact is not that one slogan could be so much more effective than another, but that thousands of dollars were spent in propagating such slogans without any more serious effort to measure their efficiency than was represented by the armchair judgment of an advertising expert. Link's study was not carried out until the campaigns had actually been under way for months. Let us recall the automobile maker. Would he for a moment go ahead with production on a car if he had nothing better than an expert's surmise that it would work? If he did, we should have one motor car with 3 or 4 times the efficiency of another in the same price class.

The public museum offers an almost ideal example of the practical value of the experimental approach to the public mentality. If we make a possible exception of the technical study collections which are displayed for the benefit of scholar and connoisseur, we may properly say that the public museum is simply an intricate pattern of psychological stimuli. It functions only in so far as it has some actual influence upon the thoughts, feelings, and actions of its visitors. The

setting up of new displays, the development of lecture courses, the labelling of the exhibits: all these are merely preparatory steps. The museum is not effective until certain dynamic relations arise between its formal physical features and the public that flows through its corridors. Yet, until 1925 no serious effort was made to attain objective, reliable knowledge of what the public museum does to its visitors. Since then a large number of the basic problems of museum functioning have been at least touched by experimental and observational procedures.

Consider first the sheer size of the museum building. Do people act differently in large and small museums? Visitors have been picked up upon their entrance into the building and followed, without their knowledge, through the course of their visit. Each stop has been recorded as to location and length. The speed of travel early and late in the visit has been determined. From such results it has been possible to show that the large museum is large at a cost. A person confronted with 1,000 pictures shows in his behavior the competition for his attention. It might seem upon first thought that such a finding has only academic interest, because big museums are not likely to make voluntary reductions in size; but the big museum is constantly making decisions as to the size of its public displays. Some of the best administrative work in the museum field has consisted in setting aside for study purposes objects that had formerly distracted and consequently hurried the ordinary visitor.

Every museum gallery and corridor presents in its size and shape problems that only the observational method can solve. We have found that under ordinary circumstances—that is in relatively symmetrical buildings and rooms—there is a strong tendency for the public to bear to the right. This tendency has shown itself to be remarkably similar in different museums and even in different cities. About 75 per cent of the visitors bear to the right and about 25 per cent to the left. This finding becomes of the first importance if we wish to arrange paintings or cases in such a manner as to tell a continuous story. But before these results were obtained, there was a persistent tendency upon the part of curators to lay out exhibits in direct opposition to this habitual line of march. Working from blue prints the eyes have moved to the left and then around the building as they would read a line of print. But the visitors have continued to walk first to the right and then around to the left. One museum which I recently visited had screaming signs to force people to go first to the left in order to fall into the chronological order of the exhibits, but there would have been no reason to erect signs if the natural routes of

visitors had first been considered. There are many more findings obtainable regarding the influence of door position and of rooms of peculiar shape, but it is safe to say that if curators without the aid of controlled observations missed this distinction between right and left walls, they are equally in need of such observations to determine the attention values of less obvious locations.

Another purely formal problem involves the optimal use of a given amount of exhibition space. During the last few months intensive investigations of this problem have been carried on in the Buffalo Museum of Science and in the Pennsylvania Museum of Art. Earlier laboratory work had shown that the crowding of displays may play a more pronounced rôle in setting up so-called museum fatigue than do hard floors and poor ventilation. In both of the museums just mentioned it has been possible to demonstrate for a given picture gallery, or for a given case of scientific materials, definite limits beyond which the addition of objects or pictures brings about a marked decrease in interest in the gallery or case as a whole. We actually found it possible to increase the amount of time which visitors would spend at certain exhibition cases by removing some of the materials from the cases. Museum men once comforted themselves by saying that it was their duty simply to make available whatever objects of art, science, or history they might have at hand, and it was the duty of the public to select for study or enjoyment those objects that struck their fancy. These recent investigations show, however, that the multiplication of pictures or objects on display does not simply increase the range of choice for the visitor, but seems rather to increase the burden of making a choice.

Some of these studies of the museum visitor have touched upon the most fundamental conceptions of modern museum practice. In recent years there has been a great development of period rooms in the art museums of both Europe and America. In the main this has been a happy development and one which has undoubtedly increased the appeal of many a museum. But new ideas of all kinds have a way of creating new philosophies, and these philosophies are not always as sound as the ideas that have suggested them. The period room method won a number of adherents who decided that the period conception ought to dominate all art displays. Their argument was plausible. They said that lines of paintings hung on bare walls were depressing. These pictures were created for the decoration of furnished interiors and they should be viewed in the general setting appropriate to the artist's time. In other words, if furniture, rugs, hangings, clocks, bric-a-brac, pictures, and the rest could be gathered

into pleasing combinations, the naturalness of the whole scene would give the visitor a feeling of repose and increase his interest in the individual art object.

Now the method which I am urging upon you is inherently suspicious of just such convincing arguments as this. Because of the splendid sporting spirit of a museum director who, himself, is a fairly enthusiastic exponent of the period idea, it was possible to carry on experiments upon public interest to determine the influence of the setting of art objects. In the main we found that the individual object, such as a painting, fares somewhat better in the relatively abstract atmosphere of the gallery than it does in combination with period furniture. In other words, the hypothesis that the period room increases interest in the individual object because the monotony of a single type of object is broken, does not hold up under experimental scrutiny. The period room remains the best method of displaying the total art of interior decoration for a given period, but those plausible effects which it was supposed to have upon the visitor probably do not bear close examination.

Thus far I have spoken of the check which the empirical method is able to apply to current devices for dealing with public interest. But the ultimate uses of the method should go beyond the proof that present practice is or is not soundly based. It is feasible to make use of the experimental procedure at an early stage in the development of any program of public appeal. Let me cite, as an example, some recent studies of the label question in connection with paintings. Instead of taking labels already prepared by a curator unaware of the possibilities of experimental test, we decided to construct labels in such a way as to bring out the importance of the several elements in the labelmaker's technic. We distinguished the types of information that could be given in regard to a painting. The label might place the picture historically; it might say something of the technic of its production; it might explain the story; or it might attempt to explain the esthetic effect at which the painter was aiming. Having distinguished these several elements in label-making, we had labels written emphasizing some one of these elements or some combination of them. We then measured the influence of these several types of label, not upon label-reading, but upon interest in the painting itself. As a result we were able to secure labelling of a given picture which increased the interest in that picture by as much as 50 per cent. The best labels were not exactly what one would have guessed beforehand. The esthetic label, for example, had a high order of effectiveness, though many of us would have predicted a poor fate for it.

The experimental approach to the problem of public influence thus offers a constructive as well as a critical service. In one case, by developing labels through a process of experimentation, it was possible to increase the length of stay of the average visitor to the 69th Street Branch of the Pennsylvania Museum by 33 per cent. The experimentalist is far more pleased with such a finding than he is with the most dramatic debunking of traditional practices.

And now let me return from the special problems of the museum to the more general problems of public education. It has been my purpose to convince you that the public mentality is sensitive and complex. No list of motives or instincts to be found in the textbooks will give you accurate grounds for predicting the fate of a given appeal. Before experimental checks have been instituted, all we can have is a hunch. However certain we may feel that the public will be soothed by this slogan or excited by that, or that these simple facts will be readily understood by the masses, we should remember that we are evaluating our own feelings and capacities and not those of the public. The final test of a new type of carburetor is always applied when that carburetor is actually in operation on a motor car. The final test of any program of public education and appeal must wait until that program can be given an experimental circulation.

If widespread health education is to be continued on its present scale, it would pay you to set up, as the public museums have done, an experimental center where objective standards of educational efficiency can replace the hunch of the artist, the poet, and the advertising man.

Health Aspects of Fruit Beverages*

WALTER H. EDDY, PH.D., F.A.P.H.A.

Teachers College, Columbia University, New York, N. Y.

RECENTLY I took occasion to run through some of the new texts on nutrition just to list aspects of fruits as a dietary essential that had merited attention by the various authors. Here are some of the values claimed:

TABLE I

1. Good for children to meet a natural craving for sweets, to satiate without danger of excess of sugar eating or caloric intake. Also good for adults for the same reasons with special reference to the matter of obesity.
2. Good as regulators of gastrointestinal function stressing:
 - a. laxative effect or
 - b. the contribution of vitamins A, B, C, and G.
 - c. their influence on bacterial flora.
3. Good as preventive of acidosis, regulation of urinary acidity, building of alkali reserve, etc.
4. Good as sources of essential mineral elements, Ca, P, Fe, Cu, Mn, etc.
5. Exceptionally important antiscorbutics.
6. Important factors in the prevention of dental caries.
7. Important as giving palatability and flavor to diets without increasing unduly costs or calories.

These values alone would justify the significant place fruits and fruit beverages have gained in the estimation of the nutritional adviser and the research that is necessary to measure the contribution of specific fruits to the consumer; but I am not at all sure that the above list of values is complete.

During the past 5 years I have been interested in new phases of fruit contribution to nutrition, and as opinions and data on the above points are already available in texts and reprints, I felt it worthwhile to confine my presentation here to some of this experimental work as suggesting possible new values worth study and evaluation.

In 1925, Chaney and Blunt¹ reported that when 600-700 c.c. of orange juice was added to the diet of 10-11 year old girls, calcium retention was increased to a degree not explicable by the amount of calcium contributed by the juice itself. The suggestion was that in some way the juice actually increased the utilization of the calcium in other articles of diet consumed with the orange juice. If such function exists it is an addition to the list given above. It is also

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

important to know whether this function is confined to orange juice or is shared by other fruit beverages and pulps. It is further important that we learn how the effect is accomplished.

For the past 7 years I have been experimenting with this hypothesis of Chaney and Blunt. I would like to trace certain aspects of this experimentation, its findings and its perplexities which must still be resolved. Also some collateral functions that have developed in the research.

At first my studies were largely confined to the banana. You may object to my citing this work as not germane to a fruit beverage "subject," but with the development of dehydrated banana (banana powder or sugar) this fruit offers possibilities of milk modification or other forms of beverage that put it in my field of report today. My earliest studies were conducted with the coöperation of Dr. Sidney V. Haas and aimed to duplicate those of Chaney and Blunt with the banana as the fruit instead of the orange. Table II summarizes this first experiment.

TABLE II
EXPERIMENT 1.

Subjects: 3 boys at the Hebrew Infant Hospital aged 3-4 years. Basal diet built on approximately 840 gm. cooked farina, 40 gm. butter, 540 gm. milk, 100 gm. bread, 42 gm. eggs, 2 gm. biscuit, and 180 gm. potatoes daily. Actual intakes measured by nurse daily. After a period on this diet a carmine capsule was given to mark the feces and after feeding the diet was continued but with two bananas daily replacing some of the carbohydrate of the previous diet so as to make calorie intakes practically the same. Feces and urines collected during both periods and analysed.

In Chaney and Blunt's work the orange juice increased retention of both calcium and phosphorus. In this series I got increased retention of calcium with 2 subjects but not with the 3d. I got no increase in retention of phosphorus with any of the children on banana. My diet was in general not optimal for Ca/P ratio, that ratio being 0.43 during the non-banana period and 0.49 during the banana period. However the contrast between the effect on phosphorus and on calcium gave partial support to the view that the banana had, like Chaney and Blunt's orange juice, brought about greater retention of calcium. Partial confirmation only, because 1 case failed to develop this difference.

Later I had, with Dr. Haas, the opportunity to repeat these observations in part in a study of infants divided into 2 groups, 1 group on milk modified with banana sugar and the other on milk modified with cane sugar. These results are shown in Table III together with some studies made by Brown and Courtney.²

TABLE III
EFFECT OF BANANA-MILK BEVERAGE ON CALCIUM ABSORPTION

| Data | <i>Diets</i> | |
|-----------------|----------------------------|------------------------------|
| | <i>Milk and Cane Sugar</i> | <i>Milk and Banana Sugar</i> |
| | <i>Grams</i> | <i>Grams</i> |
| Wt. feces dry | 1.926 | 2.761 |

BROWN AND COURTNEY EXPERIMENT

(*Canad. M. J.* 21:37, 1929)

| <i>Data</i> | <i>Banana Children</i> | <i>Controls</i> |
|-------------------|------------------------|-----------------|
| Grams Ca intake | 1.8 | 1.92 |
| Per cent retained | 18.4 | 19.9 |
| Grams P. intake | 1.86 | 1.90 |
| Per cent retained | 21.6 | 21.2 |
| Grams Mg. intake | 0.416 | 0.329 |
| Per cent retained | 23.6 | 21.9 |
| Ca/P ratio diets | 0.97 | 1.01 |

Again results are not completely confirmatory. The modified milk series showed in every case (about 10 infants on each diet) a better absorption of calcium with banana sugar than with cane sugar, but we did not measure actual retention in this series. On the contrary, Brown and Courtney with their diets (children 5 to 13 years of age on 3 to 5 bananas per day) failed to get increase of calcium retention but did get increase in magnesium retention.

These experiments, especially mine with children on mixed diets, lacked considerable of satisfaction as to accuracy of intake figures and did not permit of as rigorous control in various matters as was desirable. I therefore next set up a series of white rat studies where these matters could be better controlled. In this series I used 6

different diets and 3 rats on each diet. The character of the diets and the analytical data compiled are given in Table IV.

These studies were illuminating on several points. It was evident that the fruit produced a definite increase in volume and weight of fecal output and that with this increased output there was less retention of phosphorus and nitrogen, as would be expected, but that if the amount of fruit was sufficiently great in proportion to other factors in the diet there was, in spite of this increased fecal output, a markedly greater absorption and retention of calcium. It is true that in the banana diets given the actual intakes of calcium were slightly greater than in the control groups; but I do not believe of sufficient difference in amount to account for the way calcium behaved when contrasted with the behavior of nitrogen and phosphorus.

Of the other data noted we were especially interested in the values of the gastrointestinal tract for it might be that the explanation of increased calcium absorption lay in the effect of the banana sugar on the development of aciduric bacteria. Such a development would make a more acid intestine and hence tend to make the calcium compounds more soluble, more readily absorbed. The effect in the large intestine seemed to confirm this view. It was felt that this effect required more study and also that a more direct method of measuring absorption than by subtraction of fecal output from intake was desirable.

In pursuit of the first objective I took occasion in connection with the study of the infants on modified milk diets noted in Table III to collect the stools and have Gram-positive/Gram-negative ratios run on these stools. In general the ratios obtained confirmed the view that the banana tended to increase the Gram-positives. The ratios on the milk and cane sugar were of the following order of magnitude: $1/6$; $1/40$; $1/18$; etc., while the ratios of the milk and banana sugar group was of the order of $1/1$; $1/2.5$; $1/0.7$; $1/1.2$; $1/0.9$; etc., to quote some of the figures actually obtained. Furthermore, when we changed the diets of some of these infants, placing those that had been on milk and cane sugar on the banana mixture and *vice versa*, we accomplished in less than a week a reversal of the previous ratios.

Such ratios from stool smears are not too conclusive as characteristic of the conditions of the entire intestinal regions. At this point I therefore enlisted the coöperation of Dr. Lloyd Arnold of the University of Illinois Medical College. Dr. Arnold attempted to study the problem with the aid of white rats and suitable technics for accurate measurement of Gram-positive/Gram-negative ratios and pH values of segments of the rats' gastrointestinal canal. The diets

TABLE V

DR. LLOYD ARNOLD'S OBSERVATIONS ON THE EFFECT OF SUGARS ON
INTESTINAL FLORA AND HYDROGEN ION CONCENTRATION

Rat Diets Used:

| | |
|------------------------------------|--|
| 18% purified casein | and 68% carbohydrate which was cornstarch, |
| 8% butter fat | dehydrated banana, sucrose, lactose, or a |
| 2% cod liver oil | mixture of lactose and banana powder. |
| 4% Osborne and Mendel salt mixture | |

Each animal received in addition to the above diet 3 per cent of dried yeast daily and one meal of cabbage and of carrots weekly.

he used, the regions studied, and the results obtained, are given in Table V.

These results partially confirm the theory that the banana sugar increases the acidic condition of the intestine. It did produce a greater proportion of Gram-positives than of Gram-negatives, but was not as potent for this purpose as lactose. The effect on the pH of the tract was not so evident in this series. Dr. Arnold, however, studied further the condition of the Gram-positive and Gram-negative organisms in each series. He made a most interesting discovery; namely, that the viability of the organisms in the different carbohydrate series showed marked differences—in general, that the banana sugar markedly reduced viability in the coli types. The data on this point are given in Table VI. This was a quite new property of the

TABLE VI

DR. ARNOLD'S DATA ON THE VIABILITY OF COLI ON DIFFERENT CARBOHYDRATES

| <i>Diet</i> | <i>Small Intestine</i> | | <i>Large Intestine</i> | |
|-------------|------------------------|---------------|------------------------|---------------|
| | <i>Stainable</i> | <i>Viable</i> | <i>Stainable</i> | <i>Viable</i> |
| Cornstarch | 10 | 1 | 10 | 10 |
| Sucrose | 10 | 2 | 10 | 10 |
| Banana | 10 | 0 | 10 | 2 |
| Lactose | 10 | 1 | 10 | 5 |
| Nursing | 10 | 0 | 10 | 5 |

fruit and immediately suggested that it might be of significance in explaining the effect of banana in the treatment of celiac disease, pyloric spasm, sprue, and other cases of intestinal disturbance which had been shown empirically to respond to treatment with this particular fruit.^{3,4,5,6} To test this point out Dr. Arnold initiated a new series of studies to determine the effect of banana powder on *B. enteritidis*.

The result of the first series is given in Table VII. If these results

TABLE VII
THE EFFECT OF BANANA SUGAR ON *B. ENTERITIDIS*
(Preliminary Report by Dr. Lloyd Arnold)

Using rat diets already described in Table V, 18 rats on each of the cornstarch and banana combination were used in this series.

Series L. After feeding the rats 4 weeks on the diets 9 in each set were fed *B. enteritidis* by stomach tube with the following results:

| Time Elapsed | Cornstarch Series | Banana Series |
|-----------------|--|---|
| After 24 hours | <i>B. enteritidis</i> in the feces | <i>B. enteritidis</i> in the feces |
| After 48 hours | <i>B. enteritidis</i> in the feces | <i>B. enteritidis</i> in the feces |
| After 3-8 days | <i>B. enteritidis</i> in the feces | Feces negative |
| After 9-12 days | Rats had diarrhea; fur was rough; animals prostrated. <i>B. enteritidis</i> in feces in practically pure culture. 2 deaths, 1 on 10th day and 1 on 11th | Animals in good condition Feces negative |
| After 13 days | Survivors recovering | All normal |
| After 14 days | Survivors normal | All normal |
| After 5 weeks | <i>B. enteritidis</i> isolated from small intestine of 5 out of 6 rats. 5 had <i>B. enteritidis</i> in spleen. 2 had <i>B. enteritidis</i> in mesenteric lymph nodes. 1 had <i>B. enteritidis</i> in liver and 1 had it in heart blood | No <i>B. enteritidis</i> recoverable from any segment of the gastrointestinal tract. Spleen, liver, kidney; mesenteric lymph gland and heart blood sterile. |

Series B. 6 rats on banana and basal; 6 on cornstarch and basal; and 6 on cracked corn only.

1. *B. enteritidis* added to drinking water for one day.
2. *B. enteritidis* given intraperitoneally.

Results:

Cracked corn series: diarrhea feces pract. pure culture on 7th day. Fur soiled and rats prostrated

Cornstarch series: 2 sick on 5th to 7th days and then recovered

Results:

Cracked corn series: 6 rats died in 48 hrs.

Cornstarch series: 2 died in 24 hrs. 2 diarrhea with recovery

Banana series: no disturbance, normal weight gains

Banana series: no visible effect on the rats

are confirmed by further studies, we have evidence of an entirely new rôle of the fruit, viz., the actual destruction of activity in *B. enteritidis* and perhaps a new use for the fruit in the handling of intestinal disturbances of colon bacillus origin.

TABLE VIII

THE EFFECT OF FRUIT JUICES ON THE RATE OF ABSORPTION OF CALCIUM SALTS

Experiment 1. The relative rate of absorption of CaCl₂; Ca lactate; and Ca gluconate in water solution.

| Salts | Per cent absorption in | | | | | |
|-------------------|------------------------|----|----|-----|-----|-------------|
| | 30 | 60 | 90 | 120 | 150 | 180 minutes |
| Calcium chloride | 29 | 42 | 46 | 62 | 71 | 66 |
| Calcium lactate | 10 | 30 | 42 | 41 | 50 | 60 |
| Calcium gluconate | 20 | 21 | 21 | 25 | 25 | 27* |

* Calcium gluconate found mainly in the large intestine after the first 30 minutes.

Experiment 2. Effect of medium of solution on CaCl₂ absorption rate.

| Solutions | Per cent absorption in | | |
|----------------------------------|------------------------|----|------------|
| | 30 | 60 | 90 minutes |
| Calcium chloride in water | 16 | 20 | 31 |
| Calcium chloride in grape juice | 30 | 44 | 44 |
| Calcium chloride in orange juice | 3 | 44 | 63 |
| Calcium chloride in tomato juice | 22 | 48 | |

Experiment 3. Repetition of Experiment 2 on grape juice.

| Per cent absorption in 30 minutes | | Per cent absorption in 60 minutes | |
|-----------------------------------|---------------------------------|-----------------------------------|---------------------------------|
| Calcium chloride in water | Calcium chloride in grape juice | Calcium chloride in water | Calcium chloride in grape juice |
| 30.35 | 4.81 | 41.07 | 70.57 |
| 27.28 | 10.00 | 46.41 | 65.38 |
| 32.14 | 10.00 | 64.28 | 64.42 |
| 28.57 | 16.92 | | 70.57 |
| | 16.93 | | 72.30 |
| | 12.59 | | 68.84 |
| | 25.59 | | 79.20 |
| | 13.46 | | 65.38 |
| | 11.73 | | 61.99 |
| | | | 65.38 |
| Ave. 29.51 | 13.56 | Ave. 50.59 | 68.40 |

While these studies were progressing in Chicago, I turned my own laboratory's attention to direct measurement of absorption of calcium in the presence of different fruit juices. For this purpose I modified the method of Cori.⁷ This consisted of feeding rats by stomach tube a measured quantity of the substance whose absorbability was to be determined (sugar in Cori's experiments) after a 48-hour period of fasting; then killing the rats at intervals of time selected, recovering the alimentary tract contents and analyzing to determine the amount

of the fed product still present. We found by studies of starved rats that a certain residuum of calcium remains in the tract even after 48 hours' fasting. This amount was found to be fairly constant for rats of similar dietary history and could be used for correcting the analytical recoveries. We have to date made use of this method to study the rate of absorption of calcium salts such as chloride, lactate and gluconate in water solution and also of the effect of solution in orange juice, tomato juice, and grape juice. Table VIII shows some typical results.

These results in general give further support to the suggestion of Chaney and Blunt, in 1925, that fruit juices may have a supplementing effect in making more utilizable other factors in food mixtures. The mechanism by which the effect is accomplished is not demonstrated by our experiments to date but several leads have been suggested and are being followed.

I have presented these experiments to call attention to the fact that we have not yet exhausted the health contributions of common fruit juices and pulps, and to suggest the desirability of further search in this field. I believe that the clinical experience with fruits in certain pathological cases, if collated and analyzed, would still further extend the list of values contributed by these forms of protective foods. I have records of sprue cases where fruit carbohydrate was handled and cereal form not tolerated. Such clinical data stimulate curiosity as to the etiological factors involved, to a comparison of fruits to see in which the property is inherent, and in which it is lacking and why. Such knowledge is a means to better preservation of health and of better selection of foods to that end.

USE YOUR PUBLIC HEALTH DEGREES

VARIOUS college degrees in public health have now been awarded to more than a thousand persons, most of whom are regularly engaged in professional health activities. As time goes on many additional degrees will be granted, so that in the future there will be a large body of specially trained sanitarians whose professional attainments will be indicated by these public health degrees.

In order that the general public may become familiar with the fact that public health is a distinct profession and requires special instruction, individuals who are fortunate enough to possess professional degrees in this subject should make a practice of using them constantly. Thus, the physician who is also a doctor of public health should write himself not merely, "John Smith, M.D.," but should put his name as "John Smith, M.D., Dr.P.H." So too, the nonmedical sanitarian who has his doctorate or certificate in public health should never hesitate to employ it as an appendage to his name when used in a professional capacity. Letterheads, professional cards, and other materials employed in connection with public health duties should always display these scientific degrees, as should articles and reports.

Those persons who have the well known degrees such as the "Ph.D." or "Sc.D." might likewise, if they have been granted in public health, write after their names, "Sc.D. (Hygiene)" or some similar indication of their professional training. The result will be that the public, by acquiring a proper appreciation of these doctorates.

in the sciences of public health, will gradually come to demand that the sanitarian of the future must be a trained scientist, and that all guardians of the public health must be appointed primarily from among those who possess the necessary qualifications. Public health degrees should, therefore, be displayed wherever and whenever possible.

ONLY THREE CENTS FOR HEALTH

ONE of the most striking charts in the recent final report of the Committee on the Costs of Medical Care* shows how "Our Medical Dollar" is spent. Out of a total bill of \$3,656,000,000 for 1929, only 3.3 cents in every dollar is spent for public health, \$121,000,000, to be exact. On the other hand, we spend 3.4 cents or \$193,000,000 on cults and quacks and 18.2 cents or \$665,000,000 on drugs of which \$360,000,000 is for patent medicines, for the most part worthless medication. Physicians (29.8 cents), hospitals (23.4 cents), dentists (12.2 cents), nurses (5.5 cents), and unclassified (4.2 cents), make up the remainder of the "medical dollar."

The American Public Health Association, from exhaustive study of the subject, lays down a standard of \$2.50 per capita for public health in urban centers, and a somewhat larger expenditure in rural communities. On this basis the public health expenditures of this country should equal at least \$300,000,000, or approximately 10 cents of the "medical dollar."

How shall we ever attain a goal of reasonable public health provision for all of our American citizens? The answer, based on the experience of the past two decades, is clear. Education, organization, and demonstration are three words that tell the story of the past and give an answer to the question of the future.

For two and a half decades the public health associations and allied groups of this country, in a nonofficial capacity and with meager resources, have been organizing, educating, and demonstrating in every part of the United States that "public health is purchasable." Cities, counties, states have been organized. Tuberculosis, venereal disease, child health, and several other special problems have been stressed. Public funds have been sought and secured for institutions, nurses, clinics, health departments, and other public health agencies. For every dollar expended by the private associations in promoting public opinion, the city, county, and state treasuries of the country have expended \$10, \$20, \$50, and in many instances \$1,000 or more.

* *Medical Care for the American People*. 1932. 214 pp., \$1.50.

The American public needs the constant stimulus of some group or groups to keep up interest in any subject of common interest, even one so vital as that of the public health. That 3.3 cents offers a challenge to all who are engaged in public health work to let their friends and their constituencies know that at least three times as much effort is demanded, if we are to reach the desired goal of \$2.50 per capita.

LETTER FROM GREAT BRITAIN

AN OUTBREAK OF ENTERIC FEVER

IN recent years outbreaks of enteric fever have been so rare that when in any particular neighborhood anything resembling a large grouping of cases occurs, it is not surprising that people become alarmed. In the case of the epidemic during the autumn months in and around the small town of Malton in Yorkshire, this was sufficient to cause a certain amount of disorganization in a variety of directions, and to arouse among mothers of families a degree of fear sufficient to lead them to determine not to send their children to school.

Incidentally also, it rendered necessary a visit to the area of the outbreak by the Chief Medical Officer of the Ministry of Health (Sir George Newman) and, following that visit, the issue of a special statement by the Ministry. In this it is shown that between September 23, when the first case was admitted to the local hospital on a diagnosis of "pneumonia and diarrhea," and November 17, 243 cases with 14 deaths had been notified.

The infection in the majority of instances is shown to have been water-borne, and to have reached the water supply from the first case by way of the drain of the hospital, later found to be seriously defective near its junction with the sewer. For some time, it appears, the bulk of the drainage, in-

stead of entering the sewer, had been deposited for an extended period, according to the statement, "subterraneously upon land immediately contiguous both to the low-lying water well and to the pumping station (by which the well water was conveyed to the reservoir)."

The dates given in the Ministry statement are extremely important, and show that the period elapsing between the admission of the first case to hospital and the beginning of the flood of notifications was almost exactly a month. It shows also that comparatively only a very short time elapsed before those in charge of the investigation were able to put their finger upon the source of infection, and to adopt precautions designed to bring the epidemic to an end.

The steps taken included the giving of attention to the drainage system, chlorination of the water supply, and protective inoculation of members of the public. Also, "the future of the water supply is under consideration both from the medical and from the engineering points of view."

REPORT OF THE SENIOR MEDICAL INSPECTOR OF FACTORIES

MEDICAL inspection of factories in this country forms no part of the duty of the health authorities, and is in the hands of the Factory Department of the Home Office. For any

account of the work done it is necessary, therefore, to turn to the report of the Chief Inspector of Factories and Workshops to the Secretary of State for the Home Department, and not to that of the Chief Medical Officer of the Ministry of Health.

The report of Dr. John C. Bridge, the Senior Medical Inspector of Factories, and successor to Sir Thomas Legge, to whose death I referred some months ago, is invariably, so far as health officers are concerned, the most important part of the Factory Report. Of that for 1931, even though it has been distinctly curtailed, this may be said. The curtailment is, of course, the result of the general conditions, and this also is responsible for a reduction in numbers in various directions.

Notifications of industrial diseases—lead poisoning, anthrax, etc.—for example, are generally the lowest for some years, and though there may be some actual improvement, it is undoubted that in great part the low incidence is a reflection of the state of the labor market. In the case of lead poisoning, which returns 168 cases as against 265 for 1930; both factors appear to have operated, Dr. Bridge's conviction being that there is today much better protection from the risk attendant upon the use of lead. Of the industries, that in which the most striking improvement has occurred is pottery, 9 cases only as against 23 having been notified. Anthrax notifications, which number 21, were only half the number for 1930 (43), and notifications of epitheliomatous ulceration (65 as against 95) were also distinctly lower.

Aniline poisoning cases, on the other hand, showed an increase from 24 to 30, and toxic jaundice, of which there had been no cases in 1930, provided 7, due to arseniuretted hydrogen, in 1931. The most frequent cause of aniline poisoning, according to the report, is absorption through the skin, and the

essentials in prevention are better protective clothing and prompt action in the case of emergencies, e.g., the result of splashing.

The great bulk of notified cases of chrome ulceration occurred among persons engaged in chrome plating, but as regulations for the processes are now in force it is probable that a reduction in numbers will occur. A number of instances are quoted in the report to show the seriousness of the risk from chromic acid in fume or liquid form. Epitheliomatous ulceration, as always, found mineral oil the commonest causative agent, more particularly in cotton mule spinning. Special attention is directed to the risks of cancer of the bladder among chemical workers employed for any length of time in the manufacture of synthetic dyes.

Very special reference is made to the subject of dermatitis, and it is shown that despite the use of preventives, as alkaline antiseptic washes in the case of oils, and ointments where chromic acid and its salts are concerned, the condition is still very common. Among causative agents, alkalies, specially soda and lime, are still the chief, with sugar, oil and dyes some distance behind. Dust and fumes and gases come in for detailed reference, silicosis and asbestosis receiving special mention under the former head, and under the latter cases of acetone poisoning.

Discussing industrial illnesses generally, Dr. Bridge draws attention to a fact very commonly lost sight of—that while there may be a relation between industry and ill-health, manual work undoubtedly does exercise definitely beneficial effects on mind and body. To an extent what happens so far as this is concerned depends upon whether or not the individual is interested in his task, and as Dr. Bridge puts it: "The uninterested worker is an industrial invalid. Interest in work leads to industrial good health."

THE FATHER OF THE ENGLISH HEALTH SERVICE

BY the death of Professor A. Bostock Hill, formerly Medical Officer of Health of the County of Warwick, and for long known as the "father of the public health service," that service has suffered a severe blow. Though he retired from office many years ago, he kept up his association with and interest in public health and preventive medicine, and despite his advanced age (he was 78 at the time of his death), up to within a few weeks of the end he had attended meetings of the Royal Sanitary Institute and other bodies with which he was connected, and which relied to an extraordinary extent upon him for wise advice and guidance. He was a clear thinker, a fine debator, and had wonderfully sound judgment. Among his other activities he had been Professor of Public Health in the University of Birmingham, and was held in great affection and esteem by many others than the large numbers occupying positions of importance who proudly claimed him as their teacher.

HEALTH WORK IN LONDON

THERE are many Londons on both sides of the Atlantic, but only one, I think, that has a population of 4,363,800 and is regarded as one of the world capital cities. For these reasons such facts as are published in the annual report on public health of Sir Frederick Menzies, the County Medical Officer of Health, are of something more than mere local interest. The population mentioned is that estimated to the middle of 1931. Actually, as revealed at the census, the population of London is falling, due mainly to movement of Londoners to districts outside the metropolitan area. The birth rate, of course, is falling, that of 1931—15.0 per 1,000—being the lowest on record.

In 1931, deaths were more numerous than in the previous year, almost en-

tirely due to influenza, and respiratory and heart diseases associated with influenza. Special note is made of the tendency shown to a decrease in deaths due to street accidents. In relation to infectious diseases, the occurrence of decreases in certain cases is also noted. Smallpox—mild type—notifications, for example, fell from 5,149 to 1,452. Of actual cases of infantile paralysis, 51 were notified. The deaths numbered 6.

The 1931–1932 measles epidemic was less severe than that of 1929–1930. The deaths in 1931 numbered 115 as compared with 1,027 in 1930. In diphtheria notifications there was a marked reduction also, from 13,411 in 1930 to 8,384 in 1931. Notifications of fevers of the enteric group were 186 as against 291 in 1930. There were 24 deaths, the lowest number ever recorded in London from this cause.

Influenza was prevalent, the deaths numbering 1,121, the figure for 1930 being 366. The epidemic continued into 1932, the deaths in the second week in that year totalling 145. Rheumatic fever deaths were fewer, while those from cancer continued to show an increase: from 6,908 in 1930 to 7,159 in 1931.

The position in relation to tuberculosis in the metropolis is very fully examined in the report. The number of primary notifications (7,732) is down, and the death rate both from the pulmonary form (0.90 per 1,000) and the non-pulmonary (0.13 per 1,000) continues to decline. At the end of 1931 the number of cases of pulmonary tuberculosis on the registers was 29,565 (16,795 males and 12,770 females), and of other forms 11,060 (5,759 males and 5,301 females). Special note is made of the increased mortality from pulmonary tuberculosis among young women. This subject was one of those discussed at the Annual Conference on Tuberculosis this year, to which, I believe, I have already

made reference. The total number of cases receiving institutional treatment was 4,872, 3,218 passing direct to sanatoria or hospitals, and 1,654 to "observation" beds. The results of treatment are analyzed carefully and exhaustively, and appear to be satisfactory. Note is made of the fact that provision is made for London cases at Papworth Village Settlement.

There is reference also to a scheme, which apparently works well, under which a certain number of tuberculous youths receive special training in gardening with a view to their subse-

quent employment in the parks department. The scheme is working well, the boys so far selected giving satisfaction and benefiting greatly.

The report contains much most valuable information with regard to work done under the venereal disease scheme also, and in relation to blind persons, mental defectives, etc., all showing the vast extent of the ground covered and the thoroughness with which the various health activities of the county council are carried out.

CHARLES PORTER, M.D.

ASSOCIATION NEWS

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

Ellis K. Devitt, M.D., Old Lyme, Conn.,
Health Officer
Clarence E. Lewis, M.D., Madison, W. Va.,
Boone County Health Officer
John H. McLaughlin, M.D., 37 Main St.,
Jewett City, Conn., Health Officer
William A. Meyers, M.D., 409 W. Main,
Norman, Okla., Physician, State Bureau of
Maternity and Infancy
William A. Powell, M.D., Box K, Martinez,
Calif., Health Officer, Contra Costa County
Gradie R. Rowntree, M.D., Columbia, Ky.,
County Health Officer, Adair County
Cyrus J. Shelton, R. F. D. No. 2, Seymour,
Conn., Health Officer of Oxford
Deering G. Smith, M.D., 77 Main St., Nashua,
N. H., Chairman, Board of Health
Charles A. Wathen, M.D., McKee, Ky., County
Health Officer

Laboratory Section

John R. Fitzgerald, 429 N. Main Ave.,
Scranton, Pa., Laboratory Director, Wood-
lawn Dairy Co., Chairman, Family Welfare
Case Committee
Arnold J. Galarie, M.D., 52 W. 74 St., New
York, N. Y. (Assoc.)

Vital Statistics Section

G. Arthur Blakeslee, 3919 John R., Detroit,
Mich., Director, Bureau of Vital Statistics,
State Department of Health

Member 1901, Fellow 1923

YEAR BOOK

The Year Book for 1932-1933 will
not be published as a separate volume,
but will be included as a supplement to
an early issue of the JOURNAL, thereby
being made available to every member
or subscriber without extra cost.

SOUTHERN BRANCH ORGANIZED

AT the initial meeting of the Southern
Branch A.P.H.A. in Birmingham,
Ala., November 14-16, a Constitution
and By-laws were adopted and officers
elected as follows:

President—E. L. Bishop, M.D., Nashville,
Tenn.

First Vice-President—J. H. Mason Knox,
M.D., Baltimore, Md.

Second Vice-President—J. D. Dowling,
M.D. Birmingham, Ala.

Third Vice-President—Margaret L. East,
R.N., Louisville, Ky.

Secretary-Treasurer—R. H. White, Ph.D.,
Nashville, Tenn.

Acting Secretary—Dorothy C. Cunningham.

Representative on Governing Council—F. J.
Underwood, M.D., Jackson, Miss.

Although active membership in the
Southern Branch is limited to full-time
health workers who are members of the
A.P.H.A., provision will be made for
an affiliated membership class, com-
posed of part-time health workers.

Dr. Kendall Emerson, Acting Execu-
tive Secretary of the A.P.H.A., at this
meeting, welcomed the Southern Branch
to affiliation with the parent organiza-
tion, and expressed the belief that the
solidarity that would develop among
public health workers in the south
as a result of this organization, would
have a strengthening influence for the
A.P.H.A.

PUBLIC HEALTH ADMINISTRATION

EARLY DIAGNOSIS OF TUBERCULOSIS AMONG CHILDREN

ELTON G. LITTELL, M.D.

Medical Director, Board of Education, Yonkers, N. Y.

THE campaign of tuberculin testing, with X-ray examination of the reactors, has been of value in what it has disclosed, and also as an example of community coöperation. A more satisfactory coördination of the activities of so large a number of individuals and of groups is difficult to imagine.

The Academy of Medicine gave its endorsement of the project, then held two meetings devoted to the subject of childhood tuberculosis, having specialists as speakers and parents, school teachers, and other lay persons as its guests. It later donated \$150 for completing the taking of the X-ray films.

The Board of Education gave its approval of the work; the principals, teachers, nurses, supervisor of nutrition, registrars, students, and school physicians administered and carried out the many details of the project.

The Department of Health supplied the tuberculin; the Yonkers Tuberculosis and Health Association conducted a splendid educational work and financed most of the X-rays; two of the hospitals reduced materially the cost of the X-ray films and donated the services of the directors of the X-ray departments in taking and reading the films; the newspapers and radio station WCOH also aided in laying a foundation for this work. This foundation was in the process of building for over a year before the actual testing was begun—a community educational program being essential to the success of an

undertaking of this nature. Letters of information were then sent to the parents by the principals with details of the testing program and included a form to be signed by the parents requesting the test, and X-ray if necessary, and giving authority to report the findings to the family physician.

After the tests, parents were notified of the results, whether positive or negative, with suggestions for the future to those who did not react to the tests and with X-ray appointments for those who did react. The parents were notified too of the X-ray findings. If the X-rays were negative, parents were urged to have other X-rays taken at appropriate intervals. With positive X-rays, the patients were urged to keep in touch with the family physician, who was also notified of the X-ray diagnosis, at what hospital the film might be seen,

TUBERCULIN SKIN TESTS

and that the patient was referred back to him for his care.

Old tuberculin, 1:1,000 solution, 1/10 c.c. was used.

No reaction other than the local skin reactions was discovered in any of the 937 tests.

SUMMARY

Of the families of the 33 pupils with positive X-rays of the chest, 15 (45 per cent) gave a family history of active

lung tuberculosis. In the 15 families who gave a history of tuberculosis, there were 21 known cases of tuberculosis of the lungs and 14 known deaths from lung tuberculosis.

CONCLUSIONS

The demonstration suggests:

1. That a smaller number of skin reactors is found among the younger pupils who have lived fewer years and so have had fewer contacts with tuberculous patients.

2. That although the skin reactors among the younger pupils are fewer in number, a larger percentage of X-rays among them was positive—suggesting that earlier infection is more apt to appear in the chest. This may be influenced, however, by the fact that the neighborhood of the junior high school has had a much larger number of deaths from tuberculosis each year than the neighborhood of the senior high school.

The demonstration proves:

That the X-ray is a discoverer of otherwise hidden tuberculosis; that the tuberculin test is an inexpensive method of discovering those who ought to have the X-ray films; and that it would be wise to test all children, especially those of the high school age and those who are known to be in contact with cases of tuberculosis.

HEALTH DEPARTMENT REPORTS

Tennessee—One of the most comprehensive health department reports published in 1932 is that of the State Department of Health of Tennessee for the period 1929-1931. In general, mortality records indicate that the state suffered relatively more from infectious diseases and less from organic diseases of old age than the United States as a whole. The tuberculosis death rate at the end of the biennium was only three-fifths as high as that of 12 years ago;

in 1929, the rate was 120 per 100,000 population.

Syphilis, if its effects could be accurately measured, might compete with tuberculosis as a cause of sickness and death. Actually, it disguises itself in so many ways, and contributes to the development of so many different symptoms or diseases, that the mere statistics of deaths attributed directly to syphilis give no idea of its prevalence and importance. Recent examinations of a large number of persons confirmed the common impression that syphilitic infection is particularly widespread in the negro population.

The basic objective of the state department is to bring the whole population under effective full-time local health service and to provide in the central organization only such services and facilities as local health departments cannot provide for themselves. In addition, the department attempts to equalize the opportunity for local health service as between the several sections of the state,

. . . for in no other public activity is the interdependence of all sections so absolutely complete. Not only does one citizen deserve as much protection as another, but disease recognizes no political boundaries.

A small, compact, well trained central staff has been recruited and developed in order that expert service can be made available to any and all local departments. The state department consists of central administration and four divisions: Vital Statistics, Sanitary Engineering, Preventable Diseases, and Laboratories. Nearly 85 per cent of the appropriation goes either for state aid of all classes or for professional services.

More than half the rural population of the state is under the protection of full-time local health work. By the end of last year, 70,500 homes had been equipped with sanitary methods for the disposal of body wastes, and 526,000 children were given medical inspection in school hygiene work. Physical defects corrected rose from 18,000 in 1925-1926 to 49,800 in 1929-1930. During the year, 53,233 immunizations were given for diphtheria, 53,121 for smallpox, and 168,208 for typhoid fever.

Los Angeles County, Calif.—The annual report of over 200 pages, mimeographed, is made attractive by an ingenious cover design, instructive charts and tables, with descriptive text. Expenditures for the year ending June 30, 1932, were 10.5 per cent less than the previous year, although the eco-

nomic depression resulted in an increase in case loads of the health center clinics. There was no epidemic of serious nature. The Health Officer estimates that public health activity in the county since 1920 has, through reduced cases and deaths, saved a financial outlay of \$45,000,000. Diphtheria, as an illustration, has been reduced from a death rate of 15.9 to 2 per 100,000 population, besides a 25 per cent decrease in cases. The infant mortality rate in 1920 was 130, as contrasted with 39 for the past year.

Several unit cost studies were made of the inspection and other activities, leading to increased efficiency in administration. The net per capita cost of health department services for the 12 months was \$1.25, including medical social service and emergency treatment clinics. These costs are analyzed in considerable detail by functions by the business manager of the department.

During the year, treatment clinics for the indigent sick were transferred to the general hospital administration. This change has necessitated careful studies of medical social service work in connection with the admission and follow-up of cases as well as in the education of the community. The county health department has exercised an important influence in the community for use by the School of Social Welfare of the University of California; it has three representatives on the Council of Social Agencies; and provided the Chairman of the health section of the State Conference of Social Work. Many public addresses on public health and medical social work were given by staff members.

In the maternity and child hygiene field, 3,722 child hygiene conferences were held, with 7,560 cases registered as having made 36,335 visits. Over 500 infants were referred to private physicians for medical advice and 439 to clinical services.

It is noticeable that in 1923 the chief cause of infant deaths was diarrhea and enteritis, whereas in 1931 the chief cause has shifted to congenital causes, thus indicating where intensive preventive work is still needed to reduce further the infant mortality rate.

In the county health department laboratory, during the past 10 years, there has been an annual average of 104 examinations per 1,000 population, at an average cost per test of \$.38. During the past year the laboratory personnel numbered 18 per 100,000 tests.

New York State—The annual report for 1931 indicates that the appropriation for state aid to counties during the year amounted to \$336,043; of this \$191,197 was for half the expenditures of county health departments. In addition, \$134,874 was appropriated for public health nurses, traveling and incidental clinic expenses, \$14,125 for sanitary inspection, and \$21,246 for hospitals, preventoria and health camps owned and operated by county governments. Forty-three counties received help in amounts varying from \$825 in Oswego to \$113,310 in Westchester County. In accordance with the State Education Law, state aid of \$417,504 was given for the rehabilitation of crippled and handicapped children.

Some of the measures taken by the

State Department of Health to combat the poliomyelitis epidemic, which started early in August, were:

1. Collection of an adequate supply of human blood serum from recovered cases
2. Establishment of emergency laboratory facilities
3. Appointment of competent local consultants on a fee basis to be available on call of physicians to assist them to make clinical and laboratory diagnosis at the bedside and to administer serum
4. Restriction of the use of poliomyelitis immune serum, as far as possible, to cases in the preparalytic stage
5. Provision for additional full-time epidemiologists as temporary assistants to district state health officers
6. Furnishing of information to the medical profession and the public generally of facts concerning this disease and of the availability of clinical and laboratory aids in diagnosis and treatment
7. Employment of additional nurses to render immediate assistance and to provide the necessary after-care

A follow-up survey is being made of all cases of poliomyelitis in districts where it has been especially prevalent during the epidemic.

The purpose of the survey is to determine, in so far as may be practicable and possible, the extent to which poliomyelitis immune serum administered in the preparalytic stage was of benefit; also, to ascertain in cases with neuromuscular involvement, their classification and the extent of paralysis.

LABORATORY

A YEAST EXTRACT MEDIUM FOR DETERMINING THE BACTERIAL CONTENT OF MILK BY THE PLATE METHOD *

E. D. DEVEREUX AND J. L. ETHELLES

Michigan Agricultural Experiment Station, East Lansing, Mich.

IN bacteriological routine plate counting of milk, water, and other food products, the main purposes of a standard medium for cultivating the organisms are to obtain a fairly accurate qualitative and quantitative estimate of the bacterial content of the food and to obtain data that will be comparable to other data obtained in the same laboratory or other laboratories. These so-called standard media, or standard tests, are constantly subject to attack from the points of accuracy, simplicity of preparation or use, cost, and time consumed. It is largely with the latter point that this paper is to deal.

In recent articles by the senior author,^{1, 2} a yeast extract medium was described which proved to be excellent for the cultivation of organisms occurring in milk, the medium being used either in the liquid or solid form. Preliminary experiments revealed the fact that this medium compared very favorably to plain nutrient agar in determining routine plate counts of milk using the technic prescribed by the *Standard Methods of Milk Analysis*.

EXPERIMENTAL

This medium differs from plain nutrient agar in that yeast extract and peptonized milk are substituted for

meat extract and peptone, and dextrose is added.

FORMULA OF YEAST EXTRACT AGAR

| | |
|-------------------------------|------------|
| Yeast extract (Difco) | 5. grams |
| Peptonized Milk (Difco) | 10 grams |
| Salt | 5 grams |
| Dextrose | 10 grams |
| Agar | 15 grams |
| Distilled water | 1,000 c.c. |

Adjusted to pH 7 and autoclaved at 15 lb. for 15 minutes.

One hundred samples of raw milk were plated according to the method as described by the A.P.H.A. *Standard Methods for Milk Analysis*. One set of counts was obtained by using

* Journal Article No. 121 (n.s.) from the Michigan Agricultural Experiment Station.

Standard Methods plain nutrient agar, and a duplicate set was obtained using the yeast agar mentioned above. The same dilution flasks were used to prepare both sets of plates in order to eliminate errors that might occur in preparing two sets of dilution flasks. The plates were incubated at 37° C. and counts were made at the end of 24 and 48 hours, the plates being removed from the incubator only long enough to make the counts.

TABLE I—SUMMARY OF DATA

| Summary | 24-hr. | 48-hr. |
|---|------------|------------|
| | yeast | yeast |
| | agar count | agar count |
| | compared | compared |
| | to 48-hr. | to 48-hr. |
| | plain | plain |
| | agar count | agar count |
| | Per cent | Per cent |
| Cases showing higher yeast extract agar count | 42 | 60 |
| Cases showing lower yeast extract agar count | 56 | 37 |
| Cases showing same yeast extract agar count | 2 | 3 |
| Maximum increase in yeast extract agar count | 320 | 470 |
| Minimum increase in yeast extract agar count | 5 | 1 |
| Maximum decrease in yeast extract agar count | 64 | 59 |
| Minimum decrease in yeast extract agar count | 1 | 1 |
| In those cases where yeast agar counts were higher; average increase | 78 | 84 |
| In those cases where yeast agar counts were lower; average decrease | 27 | 23 |
| All cases considered; average difference (increase) in yeast agar count | 18 | 45 |

RESULTS

From the data obtained comparisons were made of the counts obtained in 24 and 48 hours on the yeast agar and the 48 hour plain agar counts.

A summary of the data is given in Table I, while in the bar graphs are given the cases in which the yeast agar counts were either higher (increases) or lower (decreases) than the plain agar counts, grouped according to per cent difference; and also the number of cases in each group. Averages of the data given in the graphs are presented in the table as the second and third items from the bottom. In the graphs it will be noted that the majority of the cases of lower yeast agar counts (decreases) are in the region of relatively low percentages. Although the cases of higher yeast agar counts (increases) extend entirely across the graphs there is, in each graph, a rapid rise in the region of relatively higher percentages where no decreases ever occurred. There were two cases in which the yeast agar counts, both the 24- and 48-hour sets, were 29 and 166 times the 48-hour plain

agar counts. These cases were not used in calculating the data for the table; however, in no other cases were the data withheld.

Returning to the table, it will also be noted that when the results of all the samples were considered the yeast agar gave counts in 24 and 48 hours which were on the average 18 and 45 per cent, respectively, higher than the 48-hour plain agar counts. This brings out at least two points, namely: that yeast agar counts made at the end of 24 hours will on the average be comparable to plain agar counts at the end of 48 hours, thus resulting in a saving of 24 hours; and 48-hour yeast agar counts will on the average be appreciably higher than similarly made plain agar counts. The types or organisms which appeared on the two media were essentially the same, the difference being that

the yeast agar promoted a more rapid growth of all the organisms.

SUMMARY

A yeast extract agar medium was described and when used for determining the bacterial content of milk by the plate method gave counts at the end of 24 hours' incubation which were on the average comparable to plain nutrient agar counts made at the end of 48 hours, resulting in a saving of 24 hours for the completion of the test. Also it gave counts at the end of 48 hours which were on the average 45 per cent higher than similarly made plain agar counts.

VITAL STATISTICS

Plague in British India, 1896-1931

—Plague entered British India through Bombay in 1896, and rapidly secured a foothold throughout the whole Presidency; by 1902 it had spread to the Punjab, and a little later the United Provinces were involved. The incidence of the disease was at its worst in 1907, when no less than 1,160,000 inhabitants of this country died as a result of it. But since that year, there has been an almost continuous decline in the death rate, and some sanitarians believe that the disease, as an endemic infection, will soon cease to occur in India altogether. The reasons for this progressive reduction in the number of attacks are obscure, but appear to be connected with an immunity in some way acquired against the disease in this country by rats.

During the calendar year 1929, the total number of deaths from plague recorded throughout India amounted to no more than about 70,000, and the figures for the first quarter of 1930 were so satisfactory as to give reason for suggesting, in a previous report, that the depredations of the disease during 1930-1931 would be less than they had been for many years past. These anticipations were fulfilled. The customary seasonal rise in the mortality rate took place during the months of March and April, and the incidence of plague was for a time rather severe in the Eastern Districts of the United Provinces and in the Belgaum and Dharwar Districts of the Bombay Presidency; but despite this, the total number of deaths reported during the year was only slightly over 20,000, which

is the lowest figure reached since 1898—the year immediately following that in which plague was introduced into India. The improvement was most pronounced in the Punjab and the Western portion of the United Provinces.—Calcutta: Government of India. Central Publication Branch, 1932, *India in 1930-1931*. p. 418.

The Diabetes Record of 1931—Diabetes, regardless of the insulin treatment and other advances of medicine, continues to increase. The diabetes death rate of 50 American cities, which in 1931 had a combined population of about 31,000,000, increased from 15.9 per 100,000 in 1912 to 24.6 in 1931. This is the highest rate which has ever been recorded for this country. The actual number of deaths in these cities increased from 6,890 in 1930 to 7,610 in 1931, or 9.1 per cent.

A study of the mortality from diabetes in 184 American cities in 1930 and 1931 shows increases in the latter year in 97 cities, decreases in 85, and the same rates for 1930 and 1931 in 2 cities. In 11 of these cities the rate exceeded 35 per 100,000, and in 6, it exceeded 45. The cities with rates above 45 in 1931 were Oak Park, Ill. (73.2); Atlantic City, N. J. (51.4); Madison, Wis. (46.5); New Haven, Conn. (45.5); Paterson, N. J. (45.4); and Syracuse, N. Y. (45.4). No satisfactory explanation of these excessive rates in particular localities has thus far been forthcoming. To some extent, of course, the rate is explained by admissions to local hospitals affording treatment to out-of-town residents, but this cannot account for more than a fraction of the extraordinary excess in the rate.

Equally puzzling are the low diabetes death rates for other localities. The 6 cities having rates of less than 5 per 100,000 were Greensboro, N. C.

(1.7); Hamtramck, Mich. (1.7); Flint, Mich. (3.0); Montgomery, Ala. (3.0); Pueblo, Colo. (3.9); and Medford, Mass. (4.8). Somewhere between these extremes must lie an explanation which as yet has not resulted in even extended local research. It is true, of course, that the low rates are mostly for comparatively small communities and possibly the result of accidental departures from normal.

Comparing 1931 with 1930 diabetes death rates in the 5 largest cities of the United States, it is noted that the rate increased from 23.9 to 27.4 in Chicago; from 25.6 to 27.1 in New York; and from 16.1 to 20.7 in Philadelphia. It remained the same (15.3) for both years in Detroit; and declined slightly—from 20.7 to 20.4 in Los Angeles. In the aggregate, these 5 cities had 3,413 deaths from diabetes in 1930, against 3,797 in 1931. There is, therefore, an actual increase in the mortality of about 11 per cent, practically corresponding to the observed increase in 50 cities and 184 cities combined.

For relative position, these American cities may be compared with 60 foreign cities, which, for 1930, show a range in rates from no deaths in Reykjavik, Iceland, to a rate of 29.5 per 100,000 for Colombo, Ceylon. Assuming a rate of 15 per 100,000 as fairly normal, there were 17 foreign cities with rates higher than 15, while the corresponding excess in 184 American cities is represented by 126 communities. Among the 60 foreign cities, only about 28 per cent showed rates above the assumed normal rate of 15, while among the 184 American cities, 68 per cent exceeded this rate. Among 14 Canadian cities, with an aggregate population of 1,875,922 in 1931 the death rate from diabetes was 12.4 in 1931, as compared with 11.4 for the same 14 cities in 1930. The rate of 12.4 for 14 Canadian cities is in striking contrast

to the 1931 rate of 22.7 for 184 United States cities with an aggregate population of 42,895,109.—Frederick L. Hoffman; *Diabetes Record of 1931. Spectator*, 129:7 (Nov. 24), 1932.

Vital Statistics for Jamaica, 1931

—The estimated population of the Island of Jamaica on December 31, 1931, was 1,050,667; males 509,465 and females 541,202. There were 3,604 marriages registered during the year as compared with 4,188 in 1930, a decrease of 584. The marriage rate in 1931 was 3.4 per 1,000 population, while in 1930 it was 4.1.

Births on the island numbered 36,173 during 1931, 18,344 boys and 17,829 girls. The birth rate was 34.8 per 1,000 of population. In the preceding year, there were 37,340 births with a rate of 37.0. Of the 36,173 births in 1931, 25,958 or 71.76 of every 100 births registered were illegitimate. This rate is higher than the 1928, 1929 and 1930 rates of 71.46, 71.47 and 71.75, respectively, though not as high as the 1926 and 1927 rates of 73.37 and 72.65, respectively.

There were 19,377 deaths from all causes registered in Jamaica during 1931, 9,704 of males and 9,673 of females, the death rate for the year being 18.6 per 1,000 of population. In 1930 there were 17,214 deaths with a death rate of 17.0. The 1931 rate of 18.6 per 1,000 is higher than the 1930 rate of 17.0, which was Jamaica's lowest recorded rate since the commencement of death registration in 1878, and slightly higher also than the 1929 rate of 18.4. The infant mortality per 1,000 births on the Island was 153 in 1931, as against 141 in 1930, 160 in 1929, 157 in 1928, and 173 in 1927.

In view of the fact that 67 per cent of the deaths registered on the Island during 1931 were not medically certified as to cause of death, an analysis

of the principal causes of death would be of no significance. In the Parish of Kingston, however, certification is much better; here more than 85 per cent of the total deaths are medically certified by cause. Analysis of the principal causes of death in Kingston shows that tuberculosis, congenital debility, diarrhea and enteritis, diseases of the heart and pneumonia are by far the leading causes of death.—*Jamaica. Annual Report of the Registrar General's Department*, 1931, 1-5.

Low Death Rates in Autumn—

The people of the United States and Canada usually have the benefit of excellent health conditions in the final quarter of the year; and this is the experience of the current autumn, to date. The death rates from October to December are much more favorable as a rule than in winter or spring, and are only slightly higher than the minimum mortality which prevails, year after year, in summer. This has been the experience of the Metropolitan Life Insurance Company among its millions of white industrial policy holders for the past 5 autumns. The average autumn death rate in this insured group was 7.5 per 1,000, as against 9.3 for the winters of the same years, 8.4 for the springs, and 7.1 for the summers. The average autumn mortality rate has been only little higher than that for the summer, as contrasted with a large increase between autumn and winter. In spring, the mortality rate improves over the winter figure due, largely, to a seasonal drop in deaths from respiratory diseases. But the spring death rate, nevertheless, is much higher than that for the autumn months.

Each individual cause of death has its own season of maximum and minimum incidence. Typhoid fever, diphtheria, alcoholism and automobile fatalities are the only ones of all the causes that show

their maximum mortality rates in autumn; and, in fact, the autumn diphtheria and alcoholism death rates for the 5-year period 1928-1932 were duplicated in the winter months. The average autumn death rate for automobile accidents was only slightly higher than the summer figure.

There are considerably fewer deaths from tuberculosis in the autumn and summer than in the other seasons. The average fall and summer death rates for this disease were less than 58 per 100,000 for the past 5 years, as against 68 and 69 in the winter and spring months respectively. The measles death rate is almost nil in the autumn, and deaths from whooping cough are also at their lowest point.

The seasonal incidence of suicide is of particular interest. In the wage earning group of the population, at least, the autumn death rate has been lower during the last 5 years, than that of any other season. For the population at large, it seems that the low point for suicide is reached during the winter season. One point is clear with respect to the white wage earning population, namely, that suicides are considerably more frequent during the spring than at any other season. The death rate reaches its peak, strange to say, in the month of May, which, many will agree is usually the pleasantest month of the year; and it is in the bleak months of December and January that people resort to self-murder least frequently.

Deaths of women from causes incidental to pregnancy and childbirth show a decided seasonal incidence. Among insured women, the autumn death rate for the 5-year period 1928-1932 was nearly 3 per cent lower than that for the summer season, more than 9 per cent lower than in the spring, and almost 16 per cent below that registered

for the winter.—*Stat. Bull. Metropolitan Life Insurance Co.* 13:5-6 (Nov.), 1932.

Population of Japan, 1920-1925—
In 1925 the population of Japan proper was 59,736,822. This was an increase of 3,773,769 over 1920, the rate of increase being 67 per 1,000 for the 5-year period. The average density of the population in 1925 was 156 per square km. compared with 147 in 1920. In 1925, there were 101 males to 100 females as compared with a ratio of 100.4 males to 100 females in 1920. In 1925 the portion of the population residing in cities of over 30,000 inhabitants comprised 21.6 per cent of the total. In the rural population there were 99.2 males to 100 females, while in the urban population there were 107.6 males for each 100 females. Native born Japanese comprised 997 out of each 1,000 of the total population; those born in oversea territories, 2 per 1,000; and the foreign born, only 1 per 1,000 of the total. The bulk of the 1925 population who were born in oversea territories were Koreans.

Infants under 1 year of age constituted the highest percentage of the total population. As age groups advanced thereafter, there was a noticeable decrease in the percentage of the population represented.

Agriculture was the source of employment for 14,128,360 persons; manufacturing industries employed 5,300,248; then commerce and finance were next with 3,188,002 persons employed. There were relatively fewer economically dependent persons in agriculture than in any other broad occupational group.—T. Hasegawa, *Bull. de l'Inst. Internat. de Stat.* 25(2):5-38, 1931; *Soc. Sci. Abstr.* 4:1672-1673 (Oct.), 1932.

PUBLIC HEALTH ENGINEERING

INCINERATION IN WASHINGTON*

JOHN BLAKE GORDON

*Director of Sanitary Engineering, Engineer Department,
District of Columbia, Washington, D. C.*

IN 1919 a privately owned rubbish salvage and incineration plant was constructed in Washington. Shortly after its construction prices for salvaged goods fell to a point at which no profit could be made and the District of Columbia took over the operation of the plant under a lease from the owners. Under municipal operation, the primary function of the salvage plant was to dispose of rubbish, but material salvaged reduced greatly the load on the furnaces. During this period of operation the plant was destroyed by fire and rebuilt, but the furnaces proved inadequate even under 24-hour operation to handle the rubbish collected by the District, not to mention that collected by private contractors, and it became necessary to dispose of all rubbish by burning on the available dumps.

At the Washington Airport dump, private parties are allowed to dump rubbish upon payment of a fee to the airport authorities of \$.50 a load. Material is deposited and picked over by a group of dump dwellers who at one time numbered over 200. This dump is fired whenever the wind is away from the city. Incidentally, a storm of protest from citizens associations and airport authorities, together with the anticipated completion of the two District incinerators, has resulted in an order

from the Arlington County Commissioners that this dump be discontinued.

Garbage reduction at the District owned plant at Cherry Hill, Va., about 25 miles south of Washington on the Potomac River, has proved entirely satisfactory, and during prosperous years has yielded considerable profit by the sale of grease and fertilizer. This fact, together with the unavoidable odors which experience at the garbage transfer station has indicated may be expected from the handling of this form of refuse, were the determining factors in the decision to make the proposed incinerators for rubbish and street sweepings only.

HISTORY OF LEGISLATION

Accordingly, in 1922 an unsuccessful attempt was made to secure an appropriation from Congress for the construction of one or more incinerators and this attempt was repeated regularly until 1929 when an act was passed authorizing the expenditure of \$850,000 for "the acquisition of land in the District of Columbia and the construction thereon of two modern, high temperature incinerators for the destruction of combustible refuse."

The first appropriation, made March 26, 1930, included an item for the retention of the services of a consulting engineer, in which capacity the District considered itself very fortunate in retaining Harrison P. Eddy, of national reputation as an expert on incineration.

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

From this appropriation, sites approved by the National Capital Park and Planning Commission were acquired and, following a second appropriation of \$300,000, ten bids were received March 17, 1931, on the basis of designs to be furnished by the bidders. Following complaint of one of the bidders, the Comptroller General of the United States ruled that it was illegal to let a contract on this basis in spite of the fact that comprehensive specifications had been issued limiting the designs and fixing the capacities. It was therefore necessary to have the consulting engineer prepare detailed designs of the furnaces, buildings, and equipment so that all bids would be made on one design. Accordingly, new bids were requested and on December 8, 1931, 24 new proposals were received.

During this controversy, the appropriation had lapsed and contracts could not be let until funds had been reappropriated. This was done, however, and on February 3, 1932, contracts were awarded to the Rust Engineering Company of Pittsburgh for the construction of the O Street Incinerator at a cost of \$321,416, and to the North-Eastern Construction Company of New York and Baltimore for the construction of the Georgetown Incinerator at a cost of \$169,268. This represented a saving to the District of \$104,000 over the lowest previous conforming bids.

Extra orders for items such as water-cooled dampers, indicating pyrometers, and other mechanical and structural changes, as well as driveway paving done by the District, have increased the cost of the Southeast plant by approximately \$18,000 and of the Georgetown plant by approximately \$5,000. Time of completion was fixed at 270 days to the beginning of tests at O Street and 260 days at Georgetown, and both plants were completed well within the contract time.

CAPACITY OF PLANTS

The act of Congress authorizing this construction requires that the two plants shall have sufficient capacity to burn all "combustible rubbish and street sweepings" produced in the District of Columbia and also grants permission to certain Maryland and Virginia communities to dispose of their rubbish at these plants. Accordingly, the two plants were designed with a conservative rated capacity of 595 tons per 24-hour day, making no allowance for certain substantial areas of grate surface and perforated grate-surrounded castings which would materially increase the plant capacities. A distribution of 425 tons at O Street and 170 tons at Georgetown was made after an intensive study of collections within the various collection districts of the city in order to reduce to a minimum the length of hauls to the two plants.

MATERIAL TO BE BURNED

In general the rubbish to be burned is highly combustible. Nearly half of it is expected to be paper or materials made from paper, but there is a substantial portion which is incombustible, such as metal, glassware, and leather. When delivered to the furnaces, this material is very loosely packed and its combustion proceeds rapidly. In times of heavy rain, however, it will be very wet, and in all probability, auxiliary oil burners will have to be used. Leaves to be incinerated at certain times of the year may also be either dry, loosely packed and easy to burn, or they may have a moisture content equal to that of garbage. Street sweepings, other than leaves, heretofore used as filling material on the dumps will also be incinerated in these plants.

DESCRIPTION OF PLANTS

The buildings each have a low receiving room along one side and a high

main section, with a manifold flue out-of-doors connecting chimneys and furnaces. Provision is made at O Street for the future utilization of heat to provide power by the construction of boilers between the chimneys and the building proper.

Incoming trucks pass over weigh scales where weights are recorded before the trash is dumped into the receiving bins. These bins extend nearly the length of the buildings and have capacities of 50,000 cubic feet at O Street and of 25,000 at Georgetown, to provide sufficient storage capacity to operate full time. This storage is necessary, since collection is concentrated into 8-hour days, while the furnaces are operated 24 hours a day. It is not, however, intended to store material beyond a period of 1 day. Two cranes at the first named plant and one at the second handle the fuel from the bins into the charging hoppers on the charging floors and are rated to perform 35 definite duty cycles per hour at full load.

The charging hoppers have air operated gates which permit the stoker on the floor below to admit charges of 1 yard each to the furnaces at will. After combustion, the resultant ashes are automatically quenched and discharged through water-sealed ash gates, hydraulically operated, directly into trucks at Georgetown and into an ash car at O Street. This car in turn empties into a semi-automatic skip hoist which raises the ashes into a bin where they are temporarily stored until they are loaded into trucks for transportation to the dumps. Ashes from Georgetown will be used in filling low land at Foundry Branch just west of Georgetown University while the ashes from O Street will be used in the Anacostia Park development.

CONCLUSION

Official tests have been almost concluded at Georgetown and are about to be started at O Street. These tests so far indicate satisfactory construction and design and have shown that it will be possible to operate well within the estimated figure of \$2.40 per ton, a figure obtained by a survey of various plants of like nature in several eastern cities.

Just previous to the award of the contracts, a manufacturer complained to the Comptroller General of the United States that the designs prepared for the District excluded his equipment. The Comptroller General ruled that there was no legal basis for his complaint. Later it was claimed that these incinerators infringed a certain patent, but upon advice from the Corporation Council of the District, work proceeded on the construction, and as yet no further action has been taken.

Previous to construction, the work was under the direct control of Major D. A. Davison, then Assistant Engineer Commissioner. The actual construction was carried out under the general supervision of the Engineer Commissioner, Major John C. Gotwals, with direct control invested in Harrison P. Eddy, Jr., the consulting engineer, and A. B. Greene, the resident engineer.

NOTE: It should be noted that technical descriptions of these two incinerators have been purposely avoided as requiring more space than is available. A detailed description of the design and operation of the District incinerators was prepared by Harrison P. Eddy, Jr., of the firm of Metcalf and Eddy, Engineers, Boston, Mass., and was delivered by him before the Sanitary Engineering Division of the American Society of Civil Engineers at Atlantic City, October 6, 1932. Copies of this description have been prepared and may be obtained by those desiring them.

A STUDY OF ZINC CONTENT OF CERTAIN WATERS AND ITS RELATION TO U. S. PUBLIC HEALTH SERVICE STANDARDS

THE United States Public Health Service has set a limit of 5 parts per million of zinc for waters used for drinking and culinary purposes. It has been found that there is an extremely wide variation in the solvent action on zinc of various waters. The degree of alkalinity, the amount of dissolved gases, oxygen and carbon dioxide, present in any given water will effect the rate of solution of zinc by said water. Zinc contamination, when existing, generally takes place within building limits. Zinc is seldom, if ever, present in water in street mains. Authentic cases of illness caused by

presence of zinc in water are a matter of record. The amount of zinc constituting a toxic dose, in water, is open to discussion. It is shown that the proper chemical conditioning of water will result in preventing solution of zinc. Fairhall's method for determination of zinc is recommended as being the most accurate method now available.—Abstract of paper presented by R. M. Palmer, Chemical Engineer, 500 Fifth Avenue, New York, N. Y., before the Public Health Engineering Section of the American Public Health Association at the 61st Annual Meeting in Washington, D. C., October 26, 1932.

INDUSTRIAL HYGIENE

Appointment of Occupational Health Council in Massachusetts— An Advisory body to be known as the Occupational Health Council has been recently established in the Massachusetts Department of Labor and Industries. The council will be concerned with the occupational health problems of the state, the study of which has recently been inaugurated with the appointment of an occupational hygienist. The members of the council include prominent representatives of public health and industrial medical services, labor unions, employers' organizations, social and welfare organizations, and insurance companies.

The Commissioner of the Department said:

We propose to give ourselves the benefit of the best advice obtainable from individuals and institutions concerned with the health of the working population, and we believe it no less important that these interests be kept informed of the work which we are doing. I do not anticipate the need for frequent meetings of the group as a whole, but hope rather

for the counsel of its members as it is needed, their criticism as it is called for, and their support as it is merited.

With all regard for the pressing necessity of extreme economy in government, I am confident that this new undertaking of the department will more than justify itself in the reduction of disease arising from inadequately protected industrial occupations in the commonwealth.—

Month. Labor Rev., U. S. Bureau of Labor Stat., 35, 3:541 (Sept.), 1932.

Death of Magnus Washington Alexander—Industrial hygienists will greatly regret the death of Magnus W. Alexander, an engineer by training, organizer and noted guide of the National Industrial Conference Board, which has published many important researches in industrial medicine, some in monograph form. He had headed the board since its organization in 1916.

Although born in New York, he obtained most of his schooling in Austria. Returning to America in 1893, he progressed steadily until he became engineer in charge of designing for the

General Electric Company, and, in 1918, became that company's consulting engineer on economic issues. He will be especially remembered for his comprehension of the importance of industrial safety and hygiene and his influence in promoting medical organization. Memorial articles may be found in the Sept. 20, 1932, issue of the *Conference Board Bulletin* (247 Park Avenue, New York). E. R. H.

The Dust Hazard in Air-Pressure Abrasive Blasting (Sandblasting)
—Object of the Investigation: The investigation here reported was made for the Committee on Health Protection in Air-Pressure Abrasive Blasting of the National Safety Council, of which the senior author was chairman. It was a coöperative study in which the U. S. Public Health Service coöperated with the Council. The actual field surveys and analytical work were performed by Leonard Greenburg and J. J. Bloomfield.

The object of the investigation was to determine the actual extent of the dust hazard in air-pressure abrasive blasting as conducted under American industrial conditions, to discover what protective measures were in use and to estimate their efficiency.

Air-pressure abrasive blasting is employed in two fundamentally different ways—in sandblast rooms, where the worker must operate by hand, in the midst of the sandblast atmosphere; and by the use of barrels, tables and cabinets in which the castings are exposed to the sandblast in a closed chamber, with the worker operating outside.

When such work is conducted in closed devices employing sand as the abrasive, the air of the workroom generally contains a highly hazardous dust concentration—over 90 per cent of quartz, and an average count of over 20 million particles per cu. ft. When

steel instead of sand is used, the quartz content falls to 3 per cent and the dust counts average from 8 to 15 million particles—a condition which should not cause silicosis. Studies show, however, that all four types of equipment investigated can be made safe by proper construction and maintenance.

In rooms, where the worker must operate in the actual midst of the sand blast, the dust content is, of course, enormous, averaging 155 million particles per cu. ft. with steel abrasive, and 969 million with sand abrasive.

Helmets depending on filtration are quite inadequate to protect the worker against such dust concentrations; and positive air-pressure helmets with wire mesh eye-screens are irregular and unreliable in their effect.

On the other hand, positive air-pressure helmets with glass eye-shields and an air supply of 6 cu. ft. per minute furnish complete protection to the worker under the worst conditions found in actual operation, yielding a dust content of less than 1 million particles per cu. ft. within the helmet, with 1,000.0 million or more particles per cu. ft. in the outside air and rising only to 3 million particles per cu. ft. within the helmet even when the outside air contains 4,000.0 million particles.—

Leonard Greenburg and C.-E. A. Winslow, *Arch. f. Gewerbepath. u. Gewerbehyg.*, 3, 4:577-599, 1932.

E. R. H.

Physiological Factors in Mine Ventilation in 1931—The hazards connected with work under abnormal air conditions are becoming of increasing importance from a financial as well as a physiological standpoint, due to the extension of compensation laws to include diseases caused by dusts, toxic gases, and abnormal temperatures and humidities.

The United States, with the exception of California, North Dakota, Wisconsin, Massachusetts, and Connecticut, is the only English-speaking country where silicosis is not compensated.

A summary of recent literature concerning effects on workers of exposure

to dusts is taken up in alphabetical order of countries—Australia, Austria, Canada, England, Germany, Italy, The Netherlands and the United States. In England and the United States especially there was much literature on the subject of silicosis (pp. 2–35).

A summary of recent literature on effects of toxic or noxious gases is next included by leading countries, with special reference to the United States (pp. 35–51). Abnormal temperatures and humidities follow, also by countries (pp. 51–66).—R. R. Sayers, U. S. Bureau of Mines, *Inf. Circular*, 6645, Sept., 1932 (mimeographed). E. R. H.

Compensation for Industrial Diseases—Prague—A law for compensation of industrial diseases became effective July 1. Workmen's compensation for accidents, however, has existed in Czechoslovakia since 1887. There are 25 diseases now on the list, and the government may add others. In addition to the usual industrial poisons (lead, phosphorus, mercury, arsenic, manganese, benzene, carbon surphide, carbon hydrogen, phosgene, carbon monoxide, hydrocyanic acid), a number of chemical substances, chiefly tar-products are enumerated that cause chronic eczemas and malignant growths of the skin. X-rays and radiums are also included. The list likewise contains cancer of the lungs, so frequently found in the mines of Joachimsthal. Infectious diseases resulting from occupations are covered, especially anthrax, glanders, and hookworm.

Other diseases covered are chronic changes in the bones and joints as the result of pneumatic drills and hammers. The most important group, however, is silicosis and siderosis. To this same group is added damage to the lungs by Thomas artificial fertilizer.

The last group comprises nystagmus and deafness as a result of working in mines. The accident insurance body

has the right also to give a temporary pension to a patient who is willing to change his occupation.—*J.A.M.A.* (Foreign Letters), 99, 20:1705 (Nov. 12), 1932. E. R. H.

Department of Industrial Hygiene—Studies on methods of dust estimation have been continued in association with the Miners' Phthisis Prevention Committee and the Mine Air Committee with a view of standardizing practice in the use of the dust counter (konimeter). The purpose is to secure a reasonable agreement. It is found necessary to treat the spots to be counted to remove water soluble particles and carbon in order to secure greater accuracy (in silica dust estimations). The possibilities of crucibles with filter floors of porous porcelain so that particles may be graded in terms of size-frequency is also being investigated.

In the Biochemical Department, the diet used by the mine natives has been investigated especially as regards its content in vitamin A. The livers were obtained from cases dying of pneumonia, and the amount of vitamin A was compared with that found in accident cases used as controls. The vitamin A content of the controls appeared to be quite definitely higher than that of the hospital group.—*The South African Institute for Medical Research, Annual Report Year ending December 31, 1931*, pp. 16–18. E. R. H.

Facts on Child Labor—Based on the 1930 Census returns, there were 667,118 child workers, 10–15 years, inclusive, or 4.7 per cent (1 in every 21) of the children of these ages in the United States. These figures included 431,790, or 9.2 per cent (1 in every 11) children, 14–15 years of age.

Of the gross number, 469,497, or 70.4 per cent, were employed in agriculture; 68,266, or 10.2 per cent, in

manufacturing and mechanical industries (textiles 20,625, clothing 8,650, building 7,380, lumber and furniture 4,790, food and allied industries 4,324, and iron and steel and other metals 3,236); trade 49,615 or 7.4 per cent; domestic and personal service 46,145 or 7 per cent; clerical occupations 16,803 or 2.5 per cent; transportation 8,717 or 1.3 per cent; extraction of minerals 1,184 or 0.2 per cent; and others 6,891 or 1 per cent. These figures include also those in public and professional service, forestry and fishing.

Eleven southern states (named) had from 5.5 to 24.9 per cent of their children, 10-15 years of age, employed as child workers. Nine southern states had the largest number of child workers, followed by Pennsylvania with 24,000, New York 20,000, Missouri 14,000, Illinois 12,000, New Jersey 11,000, and Massachusetts 10,000.

Limiting the figures to occupations other than agriculture, 1.4 per cent of all the children, 10-15 years of age, in the United States were found in such occupations.—U. S. Children's Bureau, Washington, D. C. (Press release received November 4, 1932.) E. R. H.

Carbon Monoxide Poisoning in Garage with Doors Open—One of the members of the staff of the Maryland Department of Health collapsed in his garage while tinkering on his automobile and with the doors of the garage open while he worked. He crawled under the engine and, realizing suddenly that he was getting light-headed, crawled out, and started out to the open door, but fell before he reached it.

A boy of 17 passing saw the figure collapsed over the fender and heard the engine running. The boy pulled the victim out into the open air, instituted artificial respiration until help arrived when the victim, still unconscious, was rushed to a nearby hospital. After the

use of oxygen for 45 minutes, consciousness was regained.

(This case serves to illustrate that carbon monoxide poisoning is a matter of the concentration of the gas wherever it is, enclosure or no enclosure. Numerous other instances are also in the literature where mishaps have occurred out in apparently open spaces, as on cinder dumps, along side of furnace rooms, bustle pipes around blast furnaces, etc.—Abstractor).—Maryland Dept. of Health, *Press Bulletin* 435, Nov. 28, 1932. E. R. H.

State Requirements for Industrial Lighting—This handbook designed for the protection of women workers contains basic considerations; the importance of good lighting from the standpoint of eye fatigue (by Janet Howell Clark), the Code of the American Standards Association for Lighting Factories, Mills and Other Working Places; a resumé of state lighting codes; and state lighting requirements other than lighting codes.

The Women's Bureau has investigated about 1,300 establishments in 13 states during the period of more than 10 years. Of these, natural lighting was reported satisfactorily in 762, and artificial lighting in 538. As a rule, simply the judgment of the bureau's investigators was used rather than instruments of precision.

In April, 1931, only 13 states had lighting codes, 19 states had no legal requirements, 8 states and the District of Columbia had some general requirements applying to all parts of manufacturing and mechanical establishments, and 10 only some general requirements applying to certain limited places only. It is to be noted that these 10 states were: Connecticut, Illinois, Indiana, Michigan, Minnesota, Nebraska, Rhode Island, Texas, Virginia, and West Virginia.—U. S. Women's Bureau, *Bulletin No. 94*:65, 1932. E. R. H.

FOOD AND NUTRITION

A Comparative Study of Milk in Bottles With Single and Double Caps—Bottled milk in transit from the filler to the consumer is subjected to temperature changes which lead to expansion and contraction causing appreciable quantities of fluid to be extruded or sucked in around the edge of the cap. The transfer of extraneous organisms from the surface of the cap and lip to the contents of the bottle depends wholly upon the protection afforded by the cap.

The object of this investigation was to determine the extent of contamination that may arise in this way and to measure the nature of this contamination and the possibility of its constituting a definite health hazard. This study was carried out under the conditions of city and rural milk delivery. The bottles of milk used in this study were closed with the ordinary single cap and exposed to the ordinary treatment of transportation and delivery. Bottles of an exactly similar sort and similarly exposed but protected with an additional hooded cap were used as controls. These tests were carried out in the period of April to July, incl. The samples analyzed represented in each case the last deliveries of the day.

Volume changes in bottled milk, which may occur under actual conditions of handling, were also studied. Observations were made under conditions of rising and falling temperatures and recorded time intervals. The bacteriological determinations employed were as follows:

- (a) Total count on the cap
- (b) Test for *B. coli* on the cap
- (c) Test for anaerobes on the cap
- (d) The *Standard Methods* bacterial count of the surface of the cream
- (e) Bacterial count of the whole milk

The tests on the cap were made after removing the outer cap or directly from the top of the single cap bottles. The results of this study are summarized as follows:

1. Significant volume changes in milk may result from differences in temperatures encountered.

2. Bacteria were more numerous on the single caps than on the inner protected caps. Anaerobic sugar fermenting organisms were found on single caps but not on the others. Positive tests for *B. coli* were obtained in 66 (61 per cent) in the single capped series and in 12 (13.6 per cent) of the protected cap series.

3. The bacterial counts of the surface cream averaged from 51 per cent to 121 per cent greater in the single capped bottles than in the double capped bottles.

4. *B. coli* was present with greater frequency in the surface cream of the single capped bottles than in the doubly protected bottles (47.5 per cent as compared to 10 per cent).

5. The bacterial counts of the whole milk averaged between 38 per cent and 64 per cent higher in the single capped samples.

The authors suggest that under certain conditions at least, milk in bottles sealed with the ordinary disc type cap may present a definite hazard to health.—M. L. Isaacs and I. Zeiber, *J. Hyg.*, 26:806 (Nov.), 1932.

Numbers and Types of Organisms Found in Certain Products Used in Infant Feeding—Various samples of powdered milk products were examined bacteriologically to ascertain the numbers of organisms present and to classify the bacteria into groups as cocci, spore-formers, gelatin liquefiers, chromogens, coli-like organisms and hemolyzers. The 20 samples examined consisted of 9 milk modifiers, 2 lactic acid whole milks, 1 synthetic compound, 3 modified milks, 1 protein milk, 1

special milk food and 3 powdered milks.

In 6 of the 9 milk modifiers the predominating organisms were spore-formers; in 1 milk modifier streptococci constituted the greater part of the flora; in 1 similar product short bacilli predominated and in 1 other sample cocci, short bacilli and yeasts were present. In the 9 milk modifiers examined the total counts ranged from 37 to approximately 32,000 per gm. of powder. Spore-formers, as few as 7 per gm. in one sample and as many as about 30,000 per gm. in another sample, were found in the milk modifiers. One of the samples contained no gelatin liquefiers, the others containing liquefiers ranging up to 3,900 per gm. No molds were present in 2 samples but in the other 7 samples molds were found ranging from 2 to 175 per gm. Eight of the 9 samples contained hemolyzing bacteria, the maximum being 9,783 per gm. found in one sample.

The predominating organisms in the 2 lactic acid milks were staphylococci and streptococci. Total counts on these 2 samples were 2,625 and 5,975 per gm. Spore-former determinations showed 80 and 1,342 per gm. One sample contained 20 gelatin liquefiers per gm.; the other contained some 400 such organisms per gm.

Molds were present in both samples, reported as 15 and 37 per gram. Also both samples contained hemolyzers (640 and 722 per gm.). Examination of one sample of synthetic compound showed a total count of approximately 21,600 per gm., spores about 2,800 per gm., gelatin liquefiers 286 per gm. and hemolyzers approximately 11,000 per gm. The organisms were mainly diplococci.

In the 3 samples of modified milks streptococci and spore-formers were found. The total counts on these samples varied from about 5,600 to 12,000 per gm.

Differentiating into groups the following figures are reported for the modified milks examined; spore-formers between 466 and 7,658 per gm., gelatin liquefiers between 210 and 3,800 per gm., molds between 0 and 41 per gm., and hemolyzers between 940 and 4,133 per gm.

Examination of one sample of protein milk showed the following results: total count 350 per gm., spore-formers 43, gelatin liquefiers 19, molds 42, and hemolyzers 24 per gm. The organisms in this product were cocci and short bacilli.

One sample of special milk food was examined showing: total count 6,150 per gm., spore-formers 358, gelatin liquefiers 153, molds 47, and hemolyzers 256 per gm. This sample contained staphylococci, streptococci and yeasts.

The organism found in the 3 samples of powdered milk were spore-formers, staphylococci and streptococci. In this product the total count ranged from 526 to 98,000 per gm. Differentiated into groups the following figures are given: Spore-formers from 65 to 1,000, gelatin liquefiers 47 to 458, molds 0 to 227, and hemolyzers 114 to 19,000 per gm.

No coli-like organisms were found in any of the 20 samples examined. The figures given in the report were obtained by computation, averaging the counts on all sub-samples taken from each can and from all cans of each product studied. Viridans and beta hemolytic streptococci were found in 5 different products and their presence was questionable in 2 others. Cultures of hemolytic streptococci obtained from one sample were not pathogenic for guinea pigs.—Helen A. Mattoon, *Am. J. Dis. Child.*, 44:16 (July), 1932.

Evidence of the Existence of a Dietary Principle Stimulating General Growth and Lactation—This is an extended study of effect of liver on the growth of rats as the result of pre-

vious reports in the literature as to the growth stimulating properties of both liver and lettuce when supplementing a complete synthetic diet.

The authors used a basal synthetic ration containing salt mixture, cod liver oil, wheat germ and dried yeast. Copper, although not added, is present in the mixture. Fresh ox liver was fed to 40 to 50 gm. rats at levels of 0.5 to 1 gm. per rat per day. There was a marked growth response at both levels compared to the controls but practically no difference between the 0.5 gm. and the 1 gm. supplements. The response in growth is rapid.

On autopsy no increase in adipose tissue was found. The increase is deemed much greater than could be charged to a biological variation. To determine transmissibility to offspring, rats were fed both control and liver diets before breeding. The mother received 1 gm. fresh liver daily during growth and gestation and twice this throughout lactation; the male received 0.5 gm. The young were given no liver and only the basal ration.

There was no difference in weight of the litters at birth and no marked difference for 21 days. At this point, however, a marked increase in weight occurred in the litters from liver-fed parents. The final weight of these rats ranged from 70 to 100 gm. heavier than those born of control animals. There was also evidence of a larger number of offspring from the liver-fed parents.

Equally satisfactory growth was evidenced in the young rats of liver-fed parents whether the preliminary liver feeding extended over 16 weeks or only 4 to 5 weeks prior to mating. It was also found that the liver had a stimulating effect on lactation.

Further experiments show this growth-promoting substance to be distinct from other accessory food factors, particularly with respect to vitamin B₁ or B₂ or mineral content (manganese).

The only suggestion advanced by the authors is a stimulation of the anterior pituitary gland and the liver substance has been tentatively termed by them "physin."—Leslie William Mapson, *Biochem. J.*, 26:970, 1932.

The Transmission of Vitamin A from Parents to Young in Mammals—Reports on a few autopsies of newborn children indicating a very small store of vitamin A in the liver prompted this investigation to determine the transmissibility of this vitamin from parents to the young in the case of rats. Prior to the main experiment, colorimetric determination of vitamin A was made of the liver from embryo rats. It was found that the store of vitamin A in the fetus is small and is chiefly contained in the liver.

The chief experiment was on female rats with variations in the vitamin A content of the diet from weaning to pregnancy and the vitamin A content of the diet during lactation. Rats were divided into groups receiving separately a very low vitamin A diet, a moderate diet and a diet very high in vitamin A (carotene). Some of the young were killed at birth and the vitamin A determined in the liver oil. More of the young were killed and the livers examined at the end of 21 days.

It was found that vitamin A in the liver at birth is small and subject to little variation. It was not increased with large amount amount of carotene during pregnancy of the mother. The amount is much larger at weaning than at birth and more varied, depending on the carotene fed to the mother during lactation. This increase, however, is limited, apparently due to the amount of vitamin A which can pass into the milk.

In discussing the application of this experimental work to other species, it is concluded that in human beings it is necessary to feed the vitamin A directly

to the infant to build up its reserve of this factor.—William John Dann, *Biochem. J.*, 26:1072, 1932.

The Action of Copper in Iron Metabolism—In previous studies on the rôle of copper in hemoglobin formation the test has been made of the increase on pure iron alone against iron with copper supplement. This work was undertaken to determine how copper functions in this connection.

Litters of young rats were kept with their mothers on screens until weaning at 21 days. By determining the iron content of young rats at different periods during weaning it was found that with rats raised in this manner for 21 days the iron content is about one-half that of those raised by the old method on shavings, the actual figures being 0.10 mg. iron on screens against 0.25 mg. iron on shavings. The young rats after weaning were placed on whole cow's milk. When the hemoglobin had decreased to 2 to 3 gm. per 100 c.c. of blood, the iron content of liver and spleen was determined.

The remaining rats were then given 0.5 mg. of iron as pure FeCl_3 daily. At the end of 2 weeks, 2 of these rats were killed and livers and spleen analyzed. Iron was taken away from the remainder and they were fed 0.05 mg. of copper as CuSO_4 daily. After 2 weeks these rats were killed and the livers and spleens analyzed. The 2 weeks' feeding of pure iron showed no increase in blood hemoglobin but a decided increase in iron content of the liver and spleen. On the copper substitution the increase in hemoglobin was 2 gm. as compared with 0.1 gm. on iron, and the iron content of the liver returned to about the same level as before iron feeding. The total iron in the spleen increased slightly.

These results indicate that iron is assimilated and stored in the absence of copper but is not available for hemo-

globin formation. Variation in this work was the continuation of feeding milk after 2 weeks on iron. There was a slight loss in iron content but not comparable to that when copper was fed. A comparison was also made between storage ability of the liver when organic iron was fed compared to inorganic. Livers in the animals on FeCl_3 contained about 5 times as much iron as those on hematin.—C. A. Elvehjem and W. C. Sherman, *J. Biol. Chem.* 98:309 (Oct.), 1932.

A Biochemical Study of Irradiated Milk—This work represents a study of the physical, chemical, and biological changes produced in milk—and milk fat—after excessive irradiation. The milk flows through a cylindrical apparatus with a carbon arc inside. The emanations are between 2,800 and 3,100 Angström units and of an intensity 1,260 times that of bright sunlight. Feeding experiments have shown that this irradiated milk has increased 16 times in vitamin D potency while the A factor is diminished only 14 per cent.

Milk is passed through the apparatus 8 times and then analyzed. The chemical composition is changed very little. The pH of the irradiated sample is slightly higher, accounted for by the reductions in bacterial count. Butterfat of the irradiated milk was made into butter and the butter analyzed. The chief difference here is the shorter induction period for oxidation after irradiation—20 hours compared to 17 hours.

The rate of digestion of the proteins of the irradiated milk was also determined both with pepsin and with trypsin. There was no retardation of digestion but in the case of pepsin at the end of 24 hours there was a slight acceleration in activity. In the case of pepsin the irradiated sample digested more readily during the early stages of digestion and at the end of 24 hours

was slightly surpassed by the non-irradiated sample. The rapid digestion is possibly due to a destruction of the anti-enzymes by irradiation.

Since the irradiation was deliberately excessive in these experiments the

authors conclude that in normal irradiation there would be no detectable change in the composition or digestibility of such milk.—Arthur K. Anderson and Howard O. Triebold, *J. Dairy Sci.*, 15:469 (Nov.), 1932.

CHILD HYGIENE

UNITED STATES CHILDREN'S BUREAU

THE annual report of the Chief of the U. S. Children's Bureau is always of considerable interest to those concerned with the broader aspects of child welfare. The twentieth annual report recently issued is of special value in clearly pointing out the implications of the industrial depression, as it bears upon the various phases of child health, child labor, recreation, dependency, and delinquency. The report covers the activities of the bureau in relation to the following:

1. Unemployment and child welfare
2. Research and general educational work in maternal and child health
3. Extent of assistance granted under mothers' aid laws
4. Prevention and treatment of delinquency
5. Coöperation with state, county, and insular public-welfare agencies
6. Industrial hazards affecting working minors
7. Employed boys and girls in Rochester and Utica, N. Y.
8. Current statistics in child welfare and related fields
9. Legislation affecting child welfare
10. State child-welfare commissions
11. Publications issued, in press, and in preparation

The Children's Bureau is now the only Federal agency compiling reports relating to unemployment relief. . . . Since January, 1932, monthly bulletins have been issued by the Children's Bureau in planographed form showing trends in relief expenditures and number of families aided, and meals and lodgings for transient and homeless persons, in

136 cities of 50,000 and more. More than a thousand agencies or divisions of agencies have been coöperating in the project. . . .

The report of the study of maternal deaths in 15 states, made in coöperation with the state boards of health and state medical societies, was reviewed in great detail by individual members of the bureau's obstetrical advisory committee, and was considered at a 3-day meeting of the committee held in January, 1932. Because of the great value of the material the committee recommended further statistical analysis of a number of points, and the publication not only of the detailed technical report of interest to obstetricians but also of a condensed report for more general use. Revision of the detailed report is nearing completion.

A survey of the unusually high infant and maternal mortality in New Orleans has been undertaken in collaboration with the New Orleans Parish Medical Society, the departments of pediatrics and obstetrics of Tulane and Dillard Universities, the Child Welfare Association, the city board of health, the Touro Infirmary, and other agencies. Interest has been focused on the relation of the death rates to such factors as age, race, hospitalization, preventive care, attendant at birth, and district of the city in which the deaths occurred. Statistical analysis is being made of the infant mortality rates for children born in New Orleans during 1930 (the most recent year for which complete birth and death data are available) and of maternal mortality rates for 1929, 1930, and 1931. A survey of the facilities available in New Orleans for the care of infants and young children and for maternal care is being made by physicians of the bureau staff, and the report will cover all agencies and institutions which offer facilities for preventive as well as curative care. In addition, the bureau's consultant in obstetrics

has investigated currently the maternal deaths occurring in the city during the calendar year 1932 and reported the findings to a committee of the New Orleans Parish Medical Society. It is the purpose of this committee to study the data presented and to decide as far as possible whether or not the deaths should be considered as preventable. . . .

Short, intensive courses in obstetrics (given on request of state departments of health and county medical societies) for doctors in active practice, carried on for 2 years through the coöperation of the medical school of Emory University in Atlanta, Ga., were extended during the past year to rural communities in Kentucky and Mississippi. Courses are scheduled for New Hampshire, and the work is to be completed in Mississippi and Kentucky during the present fiscal year.

Analysis of material collected in the New Haven study of neonatal morbidity and mortality has continued. Because prematurity is the chief cause of neonatal deaths a special study of the care given premature infants in a number of communities is being made, 91 hospitals in 22 cities have been visited during the past year. The object of this study is to determine: (1) The provision made in hospitals for the care of premature infants and the type of care given; (2) the mortality from prematurity. It is well known that the smaller the premature baby the less the chance of survival, so that total mortality figures (usually the only ones available) are not so valuable as figures compiled by weight groups. Therefore, the coöperation of the hospitals visited has been sought in compiling mortality figures in four groups according to weight at birth. . . .

During the year the bureau undertook a short study, in coöperation with the Social Hygiene Society of the District of Columbia, of the problem of the exclusion of children from schools in the District because of venereal disease in an infectious stage. Reports indicated that such exclusion was often for relatively long periods; for example, it was stated in a recent health and hospital survey made of Washington under the auspices of the Washington Council of Social Agencies that 21 of 43 children under treatment at the social hygiene clinic of the District Department of Health on a given day had been excluded from school for one to four years. The purpose of the bureau's study was to determine, if possible, the actual extent of the problem, so that the results might be used as a basis for constructive planning for these children from the educational and social, as well as medical, point of view. Three hundred and twenty-one children were listed

as excluded from school because of venereal disease by 4 agencies whose records were checked in detail. . . .

The trend of infant mortality in the United States from 1915 to 1930 was definitely downward, the average annual rate of decrease amounting to 3.1 per cent. The expected rate for 1931 on the basis of the 1915-1930 experience would therefore be between 67 and 55. The provisional rate, 62, is within these limits of expectation; the reduction is slight when the decline during 1915-1930 is considered but important in view of prevailing economic conditions. . . .

The latest figures giving infant mortality rates by cause of death are for 1929. In the 1921 registration area referred to, during the period 1921-1929, there is a statistically significant downward trend in infant mortality amounting on the average to 2 per cent annually. In the rates from natal and prenatal causes the decrease was about 1 per cent each year, in epidemic and communicable diseases about 4 per cent, and in gastrointestinal conditions 8 per cent. The mortality from natal and prenatal causes reflects the prenatal care the mother receives and the care for both mother and baby at the time of childbirth as well as the neonatal care of the baby. Popular education as to the importance of breast feeding, the proper care of milk, the preparation of simple formulas, the introduction into the infant's dietary of the right foods at the right time, as well as the value of sunshine, fresh air, and good routine in the care of baby, explain the large reduction in deaths due to gastrointestinal causes. Unquestionably this popular education has proved its value and should be continued. . . .

The only cause of maternal death in the United States for which 1930 figures are available is puerperal septicemia. In the 1921 area referred to, the rates from this cause decreased from 1921 to 1930 on the average 1 per cent per annum. The lowest rate for puerperal septicemia (22.6 per 10,000 live births) was recorded in 1930. Although more than 36 per cent of the deaths of mothers, even with this new low rate, were due to puerperal septicemia, a cause recognized as largely preventable by asepsis, it is encouraging to find that the trend is now downward.

The development of widespread medical interest in attacking the problems of maternal mortality and maternal care is undoubtedly a factor in the improvement which has been noted. State medical societies coöperated in the detailed study of maternal deaths made in 15 states during the last 2 years of operation of the maternity and infancy act, and sub-

"The Town and County Nursing Service" was established with a well chosen committee to sponsor it.

The efforts of this service were directed along three lines—spreading the idea of public health nursing throughout the country, seeking qualified nurses as the demand grew, and giving the nurses guidance and encouragement to insure their professional growth and success.

One by one, to the southern mountains, to mining camps, to farming counties, to small towns, to an industrial village, went Red Cross nurses, often the first to undertake rural work in a given state, and with them went a constant stream of wise advice and encouragement.

From the very first the Red Cross realized that nurses needed special training to do this rural work and against great odds clung to high standards. The first nurse in charge of this service worked closely with the few postgraduate courses for public health nurses then in the country, and with leading visiting nurse associations, and was aided by Mrs. Reid's scholarship loan fund.

The World War had a crippling influence on the growth of the Red Cross nursing service, but at its close it received a tremendous impetus as many of the chapters which had been working at high pitch now turned their attention to community welfare needs. Red Cross nurses returning from military service were available for rural positions, and many hundreds were rushed to postgraduate courses on scholarships. National Headquarters increased its supervisory staff both in the office and in the field to keep up with the enormous demand for nurses in the rural communities and to direct the work into safe channels. At the height of the boom period the Red Cross had 2,100 public health nursing services which it had launched.

As war surpluses dwindled chapters

began to think of getting tax support for their public health nursing services. Many transferred them to school boards and county health departments for financing after the demonstration had been made. Other chapters entered into partnership with public agencies in financing nursing services, and this proved a sound principle.

In the last few years the Red Cross has turned its activities to providing more nurses to meet the needs more adequately in a given community, and to refining its nursing procedures. Its thrice revised manual on rural school nursing is the leading textbook in this field.—Elizabeth A. Fox, *Twenty Years of Red Cross Public Health Nursing*, *Red Cross Courier*, XII, 6:173-174 (Dec.), 1932.

It would be interesting to know the number of states in which the American Red Cross was responsible for the establishment of a department of public health nursing in the state board of health. In 1920 the Red Cross nursing field representative for Indiana became also the director of the Department of Public Health Nursing for the State Board of Health. The state furnished her office but the American Red Cross continued to pay her salary and expenses until a few months later when the State Tuberculosis Association began to share equally in financing her. Later the State Board of Health took over all the financial responsibility for the department.

It would be difficult to overestimate the influence the American Red Cross had in establishing both city and rural public health nursing services in Indiana. Official funds are usually not forthcoming to finance a nursing service unless a demonstration has been made for from 1 to 4 years. The Red Cross chapters and county Tuberculosis Associations furnished funds and supervision for the demonstration here.

Now when official funds are again

health matters she may forget that the family physician must assume the responsibility; potentially he is the most important cog in the working out of preventive medicine.

There are many fair minded physicians who are more content and easier in their minds when the public health nurse does not visit their patients. The nurse who criticises the physician would soon cease if she had to assume his responsibilities for only a short time.

Those interested in furthering the welfare of preventive medicine could not do better than in interesting the private physician in this work. It is infinitely more important to make sure of his coöperation than to attempt the training of the whole public. By the very nature of his education and work he will be the most easily interested. When the time has come that his importance is realized and full use is being made of him and when his confidence is sought and won, then will he seek out the public health nurse in his work. Then and only then will he think well of public health nursing.—

A. M. Jeffrey, M.D. The Private Physician Looks at Public Health Nursing, *Canad. Pub. Health J.*, XXIII, 10: 459-463 (Oct.), 1932.

As the Public Sees Us—It would be a great deal easier for the public to understand what public health is if the public health workers could only agree on a definition themselves. In the *Survey of Nursing Education in Canada* nurses were even asking themselves if nursing was a profession.

One lay person gave this definition of public health nursing, "It is not really nursing at all; it is a camouflage to call it nursing it is really the teaching of hygiene, and it is called nursing because people are more in favor of nursing than teaching; and so it is easier to get it paid for out of taxes."

The public is a composite of groups in the community, all of which have different ideas of public health nursing.

The tax payer comprises one group. He sees public health nursing as "the

latest fad to deplete his 'wad' or the last frill to empty the tradesman's till." The best way to meet this gentleman is to subject him to a steady drip of information as to the cost of public ill-health.

The individualist is in another group. He likes independence of mind and body and dislikes "molly-coddling." In self defense we need regulation of public health in our modern communities; public health is not an individualistic matter.

There is the conscientious objector whose religious faith or social prejudices make him look askance at any attempt to coerce him in health matters. Simple statements as to the achievements of public health in saving child life, and in reducing infant and maternal mortality are probably most effective in convincing him of its value.

Then there is the conscientious critic who has known a case where a public health nurse diagnosed a case or tried to treat a patient. He thinks public health nursing is an unauthorized invasion of the physicians' territory. The public health and nursing profession are with this critic in his views, but "he should not judge a stocking by its holes."

The public is a little suspicious of a nurse who lectures instead of poulticing; that is why the work of the visiting nurse has such strong appeal; it appeals to the emotion and instincts, and "the public loves to feel and hates to think."

Despite all these apparent criticisms of public health nursing the *Canadian Survey* states that the attitude of the public is 59 per cent ideal toward public health nursing. "There is a growing volume of instructed opinion behind this work despite the fact that, in this time of financial distress, economies are apt to take strange directions."—Adelaide M. Plumptre, The Public Looks at Public Health Nursing, *Canad. Pub. Health J.*, XXIII, 10:463 (Oct.), 1932.

office. Stanley H. Osborn, M.D. (as Dr. Brown, Health Officer).

Father receives first-aid. Sarah R. Addison, R.N. (as the public health nurse).

Joe discusses his future with Uncle Bert. Albert S. Gray, M.D. (as Uncle Bert).

They look for a good place to eat—Uncle Warren along. Warren J. Scott (as Uncle Warren).

They are disappointed that Cousin Stan fails to bring his little girl along. S. Harcourt Peppard, M.D. (as Cousin Stan).

Joe cuts his foot—They visit the doctor's office. Millard Knowlton, M.D. (as Doctor Millard).

Betty has a good time at an amusement park, Cousin Henry along. Henry P. Talbot, M.D. (as Cousin Henry).

They stop at the Lee Dairy for milk—Friend Lee Mickle (as an old friend, Mr. Lee).

Joe and Cousin Larry make a rush trip to a school. Lawrence A. Fagan (as Cousin Larry).

They are curious about a drive for funds for a dental clinic—Uncle Clyde along.

The family included: father, William C. Welling; mother, Elizabeth C. Nickerson and Ruth A. Kearns; Joe, aged 17, J. Henry Giles of the Bureau of Sanitary Engineering; Betty, aged 14, Jean Evans of the Bureau of Administration.

For mimeographed copies of the series send 10 cents to Elizabeth C. Nickerson, State Dept. of Health, Hartford, Conn.

LOW COST DIET

"Publications On Low Cost Diet," issued by Social Work Publicity Council, 130 East 22d St., New York, in a much revised and amplified edition is divided into two parts. One part lists leaflets, folders and booklets for health and social workers, and administrators of food budgets. Another part lists material suitable for distribution, or for reproduction for distribution. 5 mimeographed pages. 6 cents.

"Thrift in Food For Health Protection," by Lucy H. Gillett. 4 pp. Secure from a state or local tuberculosis association. "Health During the

Growing Period," "The Health Account of the Adult," "The Best Food Values at Minimum Cost." Not for lowest income groups. *Samples free* from National Tuberculosis Association, 450 7th Ave., New York.

"Good Food for Little Money" to protect the health of Children, by Lucy H. Gillett. American Child Health Assn., 450 7th Ave., New York. 2 pp. A very condensed "guide to the wise and economical selection of foods for the family." 1 to 3 copies, 3 cents each; 4 to 9 copies, 1 cent each. Lower rates for quantities.

"Good Food For Little Money," by Helen MacMurchy, M.D., Dept. of Pensions and National Health, Ottawa, Canada. 14 pages; 3 x 6 inches; in English or French. "The trouble in Canada at present is not so much that we cannot get food. We can generally get food. But we need to choose our food better, to cook it better, and to use it to the best advantage."

"Food Helps For 1932-1933," a 4-page folder, New York Tuberculosis and Health Assn., 386 4th Ave., New York. Lists publications for the worker and for distribution, and motion pictures and posters offered for use in New York City. No copies of the folder are available.

A course in emergency nutrition problems was offered in December by the Boston Health League and the Boston Council of Social Agencies. Limited to 100. Topics: "Nutrition and Social Welfare"; "Low Cost Budgets—How Essential Are They and How Practical Can They Be?"; "Low Cost Budgets—How Can We Teach Families to Follow Them?" "Tulsa Plans and Other Makeshifts in Food Budgets."

A series of large-page folders and leaflets has been prepared by a group of Boston nutrition services, and is distributed by the Boston Health League. They are well printed, with good, read-

able type. They are notable for the effort to teach simple nutrition facts. Several interesting devices will help the better educated readers. One device is a series of illustrated paragraphs, such as:

(Picture of milk bottle)

1 quart daily for each child

1 pint daily for each adult

gives

calcium for bones and teeth

protein for growth, muscle and repair of the body

sugar for energy to work and play

vitamins for health and vigor

One wonders how far we can go in teaching even elementary dietetic science when people are harassed with fear of having a mere sufficiency of food.

HONORABLE MENTION

To *Welfare Advocate*, Public Welfare Commissioner, Manila: for improvement in paper and printing, and for improved folding for the mails. (Much space is given to public health topics.)

To Milbank Memorial Fund, New York City: for the chapter on "Health Education" in its report for 1931. a record of varied and valuable service in diverse coöperative efforts.

To United Hospital Fund of New York City: for annual report with a table of contents.

To New York State Department of Health: for annual report with table of contents and index (although not complete).

REPORTING

The House of Open Doors is a report, but not an "annual report," of the Wisconsin Anti-Tuberculosis Assn., Milwaukee. It is a chatty, readable tour of "the old gray building on Jefferson Street" where so much is done that concerns so many people in Wisconsin. It is mimeographed, with at least one informal sketch on each of the 9 pages. Copy for 10 cents.

January 1, 1933, Commissioner of Health Shirley W. Wynne submitted to the Mayor of New York City a 9-page review of the work of the department *with statistics for 1932*. Of the per capita expenditure of 68 cents it was reported that "less than 1 cent is spent for the work of health education including the publication of pamphlets, the preparation of radio talks, the organization of lecture meetings, and exhibits, and the issuance of bulletins of information to newspapers, magazines, etc."

CHILD HEALTH EDUCATION

"Some Recent Contributions to Health Education": A list compiled as a service to instructors giving courses in health education. American Child Health Assn., 450 7th Ave., New York. 4 mimeographed pages. Single copy *free*.

"Some References on Child Care and Training" for those conducting child care classes in secondary schools or parent-teacher groups. American Child Health Assn., 450 7th Ave., New York. 5 mimeographed pages. Single copy *free*.

"Safety and Health of the School Child," by J. F. Rogers, M.D., of U. S. Office of Education. 29 mimeographed pages. 1932. "A self-survey of school conditions" covering "Physical conditions of the school plant affecting the life and health of the child," "Mental conditions of the school influencing health," "Bodily conditions of the child affecting his life and health and that of others," and "Teaching staff," with "reading references." 10 cents. Superintendent of Documents, Washington, D. C.

Journal of Home Economics, Baltimore, carries considerable material on nutrition and its place in health education in the schools. *Sample free*. In Nov., 1932, issue: "Nutrition Needs of the School Child and the Responsi-

bility of the Home Economics Teacher," by Lydia J. Roberts; "Health Education in the Public Schools of Akron, Ohio," by Martin and Davison. (The last is a National Dairy Council project.) 30 cents.

Again the Child Health Education Service of the National Tuberculosis Assn., 450 7th Ave., New York, invites women candidates for a full tuition scholarship of \$500 at the Massachusetts Institute of Technology.

From the University of Texas, Bureau of Nutrition and Health Education, Austin, come three publications of a series: "Activities of Frogs and Toads" (4th grade; 20 cents); "Activities of Birds" (5th grade; 20 cents); "Activities of Honey-bees" (6th grade; 25 cents)—all by Jeanie M. Pinckney and Alice H. Miller. Each "is one of a series of units of health instruction published in workbook form. The purpose of these work books is to teach growth, development and social hygiene. . . . The pupil is presented with a series of problems which he solves himself."

ADVERTISING

"The Urge to Excess" discredits claims made in certain coffee and laxative advertisements. *Journal of A.M.A.*, Chicago. Nov. 19, 1932. Good to add to your portfolio or scrapbook of debunking food and drug material offered to the public for reference.

Good for similar use is a series entitled "Know-your-drugs," issued by U. S. Department of Agriculture, Washington. Ask for *Clip Sheet* issues containing the above series.

MOTION PICTURES

"There is an urgent demand for new and up-to-date films if this form of service is to be continued. The use of 16 mm. films as recommended by the Film Committee would materially cut down the cost of this service."—Ernest

D. Easton, New Jersey Tuberculosis League.

"Motion Pictures as an Aid in the Teaching of Nursing Procedures," by Anne M. Goodrich. *Trained Nurse*, New York. Nov., 1932. The value of pictures; problems in taking and using pictures. Illustrated by selections from pictures already available through Anne M. Goodrich, 108 East 38th St., New York. In 35 mm. and 16 mm., for rental or sale.

"1000 and One—the Blue Book of Non-Theatrical Films." *Educational Screen*, 64 East Lake St., Chicago. 1932-1933 edition. 128 pp. 75 cents; 25 cents to subscribers to the magazine. Classified lists of silent and talking pictures, both 16 mm. and 35 mm., free and otherwise. Includes physiology, health and hygiene.

DISCONTINUED

"Tidings," Child Hygiene Division, Massachusetts Dept. of Health, has ceased publication "for a while."

The weekly health and communicable disease bulletin of Oregon State Board of Health has lost the franking privilege. The mailing list will be limited to health officers and newspapers, and to those who will pay postage at one cent a copy.

RADIO

"Writing the Home Economics Radio Program," by Morse Salisbury. *Journal of Home Economics*, Baltimore. Nov., 1932. Reprint, 10 cents. Get a copy, change "home economics" to "health education," and you have a most stimulating and practical guide to effective radio presentation.

In same issue of the *Journal* are several editorial notes on broadcasting. 30 cents.

Radio talks during the Christmas seal sale in Ohio: "Robbing Tomorrow to Pay for Today," "Health and the Depression," "Short Cuts,"

"Dollars and Sense," "Health Consciousness," "Tuberculosis and the Press," "What Are They Singing?"

Radio talks in New York City's Christmas seal sale: "Something to Be Thankful For," "A Tiny Friend of All Children," "Youth's Greatest Asset," "Public Health in the Red," "Hidden Children," "Have You a Health Problem?" Three of the series were given over N.B.C. or Columbia chains.

EDUCATIONAL MATERIAL

"Illumination and Eyesight in Industry," by LeGrand H. Hardy, M.D. National Society for the Prevention of Blindness, 450 7th Ave., New York. 12 pp. 10 cents. For the employer, safety director, industrial physician or nurse, labor leader.

The 1932-1933 catalogue of publications, Commonwealth Fund, 41 East 57th St., New York, has sections on "Health," "Mental Hygiene," and "Mental Hygiene Pamphlets."

The Educational Department, California Fruit Growers Exchange, Los Angeles, Calif., offers a 1933 series of bulletins for food teachers and nutrition workers.

The Full Endorsement of the Advisory Council—A distinguished group of men have promised again what has been promised before but probably never realized as yet. "*Only those manufactured products which have the full endorsement of the advisory council*" "will be given a place" in the first annual New York Food and Health Exposition, Grand Central Palace, New York City, April 3-8, 1933. The "full endorsement" is promised by Dr. Wynne of New York City, Dr. Parran of New York State Department of Health, Dr. Mendel of Yale, Dr.

Rosenau of Harvard, and Dr. McCollum of Johns Hopkins.

It would be interesting to learn the procedure by which this competent group bestows or withholds its "endorsement," and how it will function when desperate space salesmen sell space to a product which is not 100 per cent endorsable. And will the endorsement cover the advertising claims made for the product, as well as for the merits of the product?

In Your State—Due to the curtailment of the activities of Cleanliness Institute, the National Tuberculosis Association has been designated by that organization as the repository and distributor of all their printed matter dealing with public health. The National Tuberculosis Association has made arrangements through its state and local associations to distribute this material to schools, industries and the general public in accordance with the general plans that have been established by the Cleanliness Institute. Any persons desiring publications of the Cleanliness Institute should make application to their state or local tuberculosis associations.

MAGAZINE ARTICLES

"Where the Normal Diet Fails," by E. V. McCollum. *McCall's*. June, 1932.

"Medicine Marches Forward," by Alva Johnson. *McCall's*. June, 1932.

"Progress will always seem slow enough. The age of miracles is past, and human ailments are too numerous and elusive to be conquered in one swift campaign."

"Birth Control: A Balance Sheet," by R. E. Baber. *Forum*. Nov., 1932. Health aspects: social and economic factors: moral and religious factors: the balance sheet.

BOOKS AND REPORTS

A Century of Public Health in Britain, 1832-1929 — By J. H. Harley Williams, M.D., with a foreword by W. W. Jameson, M.D. London and New York: Macmillan, 1932. 314 pp. Price, \$2.50.

This is a book that adds sunshine to the work of a reviewer. As a believer in the historical foundation of teaching and progress, the writer welcomes it with more than usual pleasure. In America we recognize that we owe to England the foundation of our enthusiasm for public health, or what has been called the "sanitary idea." The author says that the title of his work might well have been "The History of Public Health Prejudices."

The history covers the period 1832-1929 inclusive. All facts are easily available, since what we call modern public health is almost entirely a product of the last 100 years, though it would be ungracious to forget, for example, the Jewish sanitary laws as given in the Pentateuch, the water works system of ancient Rome, and the high degree of sanitary practice which existed in the Isle of Crete. However, most of these things had been practically forgotten, and we woke up only after Chadwick's inquiry of 1842, "the earliest example of the way in which scientific examination of the technical data of ill-health becomes the basis of legislation."

The author begins with the Poor Law Act of 1834, carries us through the Public Health Act of 1875, the attack on the Poor Law, and the Local Government Act of 1929. He considers the National Health Insurance Act (in force July 1, 1912) as perhaps the greatest social measure of this generation, and the most important influence

in medicine since the Public Health Act of 1875.

A section, 71 pages, is given to tuberculosis, in which the author traces the development of anti-tuberculosis measures, stressing the founding of dispensaries by Sir R. W. Philip, who was knighted in 1913 for his achievements; the Act of 1911, in which funds were made available for sanitariums, and the founding of such institutions as Papworth Village and Preston Hall Village. One would think from reading this section that the demonstration of the danger of bovine tuberculosis to human beings was the work of the English Commission appointed after Koch's memorable blunder in 1901. The author has apparently never heard of the work done in America at the Laboratory of the State Live Stock Sanitary Board of Pennsylvania, which published its demonstration of Koch's fallacies in April, 1902, nor of the German Commission which reported about the same time that the First Interim Report of the British Commission appeared, in 1904. Since the author is connected with the National Association for the Prevention of Tuberculosis, he should know and give history somewhat more correctly.

We must also differ with the author in the three lines he gives to Oliver Wendell Holmes concerning puerperal fever. He speaks of Holmes's work as a suggestion, and states that he did not follow up his idea. Holmes's paper was printed in 1843, and reprinted 6 times between that date and 1891. Holmes said distinctly "Puerperal fever is so far contagious as to be frequently carried from patient to patient by physicians and nurses," and also that he had abundant evidence that many

practitioners had been more careful in handling puerperal cases as a result of his warnings.

Vaccination against smallpox is treated of in Part VI, and the demonstration of its value is so clear that one finds it hard to understand the objections raised to it. Conscientious objection has hit England hard. Coercion is repugnant, but education and continuous propaganda must be pushed. The psychological side was given by the *Times* in 1858: "The English people decline to be bullied into health."

The volume closes with sketches of Chadwick, Simon, Florence Nightingale, Francis Galton, and Lord Shaftesbury, all of which are interesting. The index could be improved. The printing and make-up of the book are excellent, and in spite of some faults, we consider it one of the most interesting as well as useful books which have come to us for a long time. MAZÛCK P. RAVENEL

Medicolegal Cases. Abstracts of Court Decisions of Medicolegal Interest. Edited by William C. Woodward, M.D., LL.M. Chicago. American Medical Association, 1932. 1336 pp. Price, \$7.00.

One of the valuable features of the *Journal of the American Medical Association* is its Medicolegal Section, in which current court decisions on various aspects of medical jurisprudence and legal medicine are abstracted each week. During the calendar years 1926 to 1930, there were included in this section approximately 1,300 cases, a figure which affords an interesting commentary on the vast amount of litigation involving the medical profession, especially since a large number of these decisions were concerned with malpractice or alleged malpractice.

All of these excellent abstracts have been collected in this impressive volume, preceded by a table of cases, and followed by a comprehensive index. Each

case has an appropriate heading, indicating its salient points, and a citation is given to the volume and page in the national reporter system where the complete law report may be found. The value of these references would have been enhanced if citations to state reports had likewise been presented.

Although much more work would have been necessary if these abstracts had been arranged more closely by subjects, consultation of pertinent cases would have been facilitated by such an arrangement. It would, of course, have been impossible to do this completely, as one decision may include several important points of law. The index, which is a noteworthy feature of the book, permits of ready location of cases on topics with which the reader may be concerned.

A number of decisions on public health are included. Not all of these are indexed under "Health" or "Health Departments," however, but some will be found listed under "Food," "Vaccination," the names of specific diseases, and under other appropriate titles.

The Bureau of Legal Medicine of the American Medical Association, directed by Dr. Woodward and manned by a staff of competent lawyers, is to be congratulated on the publication of this volume, which will prove of inestimable value to physicians involved in legal matters requiring adjudication by the courts. JAMES A. TOBEY

A Guide to Human Parasitology—By D. B. Blacklock and T. Southwell. Baltimore: Williams & Wilkins, 1932. 271 pp. Price, \$4.00.

The text is intended especially for the practitioner who does not have access to a laboratory where parasitological diagnoses are undertaken and who may be required to diagnose diseases caused by animal parasites.

It will also prove valuable for medical students taking special courses in human parasitology. The discussions and definitions are intended to apply to those species or groups of parasites found in man, and not to animal parasites in general.

The text opens with a brief discussion on the importance of a knowledge of human parasites and how any practitioner can readily gain this knowledge. One chapter is devoted to the microscope, and one to the preparation of films or smears and their examination for parasites. Chapters IV and XXII inclusive deal with the various parasites affecting man. One chapter is devoted to the Spirochetacea, 6 chapters are given to the Phylum Protozoa, 7 to the Phylum Platyhelminthes, 3 to the Phylum Nemathelminthes, and 1 to a discussion of Myiasis.

Chapter XXIII consists of 11 concise tables showing geographical distribution of worms found in man, the various vehicles in the spread of human parasites, stages of parasites infective for man, parasites and tissues or organs in which they are found and the diagnostic features of parasites. Drugs used in treating the diseases considered with dosages are briefly discussed.

The text is very well illustrated, including 16 full page diagrams showing life histories of human parasites. The brevity, simplicity and clear-cut descriptions of those characters in the various parasites which have immediate diagnostic value are especially commendable features of the text.

L. HASEMAN

The Canadian Mother's Book—By Helen Macmurchy, M.D. National Health Publication No. 2, Dept. of Pensions and National Health, Canada, 1932. 228 pp.

Full of flavor and of a style all its own is this little manual for the

Canadian mother; popular, too, judging by the inscription "Eighth Hundred Thousand" on the title page. It is written in simple, colloquial language and one might well imagine that it might prove very comforting to many mothers—especially those of the less sophisticated type. Throughout the book national pride is appealed to by way of reinforcing the precepts laid down. In print and spacing, this book is in agreeable contrast to most governmental publications issued on this side of the international border.

One criticism might be made of nearly all "books for mothers," including this one. If the prospective mother is urged and expected to go to the family physician, it seems inadvisable to go into too great detail as to what the physician will do and tell her to do: there may be differences of opinion between the writer of the book and the physician, to the bewilderment of the patient.

MERRILL E. CHAMPION

Behind the Door of Delusion—By "Inmate—Ward 8." New York: Macmillan, 1932. 325 pp. Price, \$2.00.

This book was written by a brilliant newspaper man, a finished speaker, and an active figure in civic affairs, but unfortunately, according to his own confession, he was addicted to the excessive use of alcohol, so much so that after one debauch which pretty nearly ended his earthly career, he was put in an insane asylum of his own volition, where, at the time the book was written, he was still staying until he got rid of an insatiable craving for liquor. It is dedicated "To a better understanding of those on the inside by those who are not yet locked in."

All through the text there is evidence of an acute mind, a keen observer, and an analytic power. The stamp of sincerity and honesty is there, and the book will be a revelation to all who do

not know the inside workings of the ordinary mental hospital, or as they have in the past been called, insane asylums. From cover to cover, it is full of interest to any thinking reader, but especially to physicians and social workers who come up against the problem of drink. His observations of the insane accord in some respects with those of Clifford Beers in *The Mind That Found Itself*. The diagnoses of new cases by old inmates are generally correct and promptly made. Their mode of expressing this diagnosis is usually amusing. Many keep happy, but the pathos of the situation lies in the universal desire to go home. The most striking indictment in the book is of the asylum attendants, most of whom lack conscientiousness, patience, and the mental ability for the thorough study and understanding of each patient which is essential. Many are drifters, going from one asylum to another and obtaining jobs which they hold only until they are found out.

We commend the book to all who are interested in this tremendous problem of modern life. MAZŸCK P. RAVENEL

The Sputum—Its Examination and Clinical Significance—By Randall Clifford, M.D. *New York: Macmillan, 1932.* 167 pp. Price, \$4.00.

This book will serve as a valuable reference and text for physicians, laboratory workers and students. It is concise, simply written and well indexed.

Directions are given for collection of sputum specimens for examination, and the author emphasizes the importance of postural drainage as an aid to the patient in raising sputum. Methods and materials for sterilization of the sputum are discussed.

Macroscopic and microscopic examinations are dealt with separately, with descriptions given of the common findings. There are many colored plates and photographs to supplement the text.

The last part of the book is concerned with the character and clinical significance of the sputum in relation to some of the more common diseases of the respiratory tract. The author attempts to aid the clinician and laboratory worker in the diagnosis of lung and bronchial diseases by descriptions of the various types of sputum raised in each case.

He points out the outstanding physical characteristics of the sputum in lobar pneumonia, lung abscess, tuberculosis, and other diseases, together with their significance. Microscopic findings in each disease are added. Several pages are devoted to "Pneumoconiosis" or the different forms of pulmonary fibrosis due to dust inhalation. He stresses the importance of sputum examinations in such cases due to the frequency with which they are confused with pulmonary tuberculosis. Laboratory tests and technique are given to aid in correct diagnosis.

The book contains 167 pages with excellent bibliographies at the end of each chapter. C. C. YOUNG

The Purchase of Medical Care Through Fixed Periodic Payment—By Pierce Williams, National Bureau of Economic Research, Inc., New York, 1932. 308 pp. Price, \$3.00.

This report is based on the results of a survey aimed to throw light on the extent to which the people of the United States make use of the principle of insurance in order to secure medical and hospital care. The study was conducted largely by correspondence by the writer, who is a member of the research staff of the National Bureau of Economic Research, upon the invitation of the Committee on the Costs of Medical Care. Emphasis was placed on medical and hospital care "in kind," only minor discussion being given to accident and health insurance.

Consideration is given to fixed pay-

ment medical service in the lumber and mining industries of various states, to a hospital contact system, to service for railroad employees, to group clinics, community health associations, and to certain benefit funds. This will be a useful reference book for several types of students, but is hardly essential, certainly at the price, for health workers.

IRA V. HISCOCK

Normal Youth—And Its Everyday Problems—*By Douglas A. Thom, M.D. New York: Appleton, 1932. 368 pp. Price, \$2.50.*

This latest book of Dr. Thom is on adolescence. It is a very clear presentation of many of the internal experiences of the adolescent child and influences in his environment which affect his development during this period. For this reason, there is a great deal of emphasis placed upon home and school influences and their effects. Case histories are given in abundance, each one emphasizing the particular point or points that have been discussed. In this manner, Dr. Thom clarifies and illustrates the practical application of his theoretical discussions.

His presentations of sex problems and their nature are set forth with great frankness. Some may question the wisdom of this in a book that will be read so widely and, therefore, by a number of people who, for any of a number of reasons, will not be able to accept this boldness.

This very objective presentation of sex materials is certainly desirable in books whose circulation is limited to certain professional groups. However, anyone who has had any clinical experience with these problems realizes how skillfully this subject must be presented to most lay and some professional individuals in order not to produce resentment. This frankness may serve, therefore, to increase, in

the minds of many readers, their resistance to the understanding and acceptance of the viewpoints presented rather than to diminish them.

There is no discussion of the value or rôle played by religion or objective morality. As there are many people of different religious faiths to whom religion and moral values are of utmost importance in influencing their mental health, it seems that a book of this nature, concerned with the "whole" child, should have given more than passive reference to this group of influences. Moral and religious values are dominant characteristics of the healthy and well integrated individual. These values cannot be ignored in any type of constructive therapy that aims to build up the total personality of the individual.

His approach to the problems of adolescence is essentially dynamic and analytic. The influences of Freud on the author's interpretation of these problems is evidenced throughout.

The author has a very clear style with the result that this book is by no means difficult to read. It consists of eleven chapters and an index. It has much value to the person who is interested in obtaining a knowledge and insight into many of the problems that are characteristic of adolescence and especially those conditions which impede or aid the child's attempt at adjustment and development during this period.

FRANK J. O'BRIEN

Die Arbeitsbehandlung zur Reform der Lungenheilstätten—*By Prof. Dr. Hanns Alexander and Kurt Alexander, Volkswirt. Leipzig: Georg Thieme, 1932. 100 pp., 44 figs. Price, M. 5.*

This is a very fully illustrated account of recent developments in Europe, especially in Switzerland, Holland, and Germany, of the problems of employment in sanatoriums for tuberculous

patients. Employments available or in use in the institutions are treated from the standpoints of purpose, choice, adaptability, direction and control, costs with financial support and returns, selection of articles to be made, incentive, and compensation. The therapeutic values are considered, and types of intellectual occupations for middle-class patients are discussed with reference to their social and public relations.

A full account is given of the organization, administration, and details of such a sanatorium at Agra near Lugano, in which intellectual and professional work is fostered instead of handicrafts. Labor in trades and handicrafts is described in considerable detail from twelve other prominent European institutions. C. A. KOFOID

The International Medical Annual—
By Carey F. Coombs and A. Rendle Short, editors, and twenty-nine contributors. New York: Wood, 1931. 551 pp. (illus.). Price, \$6.00.

A useful volume rather difficult of adequate description in limited space. It is a kind of dictionary of "practical medicine," written by 31 men from the British Empire, mostly from England. In the language of the fly-leaf, it is "A Review of the Year's Work in the Treatment of Disease," in which they include everything from chemical therapeutics to vaccination and surgery. However, the editors inform us that they studiously omit pathology, animal experimentation and mere theories. All items are arranged alphabetically.

Typical of the treatment given the various subjects, scarlet fever might be mentioned. Following brief cross references, such phases of the disease as epidemiology, etiology, symptoms and complications, Dick test, prophylaxis and treatment are reviewed by Dr. J. D. Rolleston, while Dr. G. E. Oates handles the subject of management. Nineteen

references to recent literature are used—the reviewer often agreeing with the papers before him. It is interesting to note that the opinion is concurred in "that until a technic is available that is sufficiently precise to identify the scarlet fever organism as well as sufficiently simple for general application, the control of scarlet fever must continue without the aid of throat cultures." On the whole, the book should find a hearty welcome on every practitioner's shelf.

C. F. ADAMS

Epidemiology. Historical and Experimental—*By Major Greenwood, F.R.S. Baltimore: Johns Hopkins Press, 1932. 88 pp. Price, \$1.50.*

A generous modesty gracing fundamental scholarship characterizes this tiny volume, which contains much wisdom on one of the broadest fields within the disciplines of medicine.

Dr. Greenwood, himself a distinguished successor to the epidemiologists of history, most sympathetically appreciates and relates the merits of ancient contributions to our understanding of disease as a herd or mass or group phenomenon. We are carried in the first chapter from the book of Epidemics of Hippocrates past the foggy theories of Galen into the threshold of modern epidemiology opened to us by Fracastoro. From Sydenham, the clinical colossus, there came but little of great value to epidemiology except a conception of epidemic succession. Then follow Graunt, Henle, Farr, Simon, Ross, and Brownlee, masters and teachers, all leading directly to their peer of today, the present author.

In the second and third chapters we meet the rigorous discipline of the experimentalist, a pioneer in the new epoch wherein bacteriologist and statistician join forces to pose questions and prove answers.

Nowhere else can so concentrated a statement of the philosophy, the argu-

ment, and planned and controlled experience to elucidate human and animal herd experience with disease be found.

While the experimental experience is with communicable disease, the principles of inquiry and the reasoning involved are of no different order from those required in epidemiological study of occupational diseases of mass significance.

The *Pasteurella* and the multitude of mice as studied by Greenwood and Topley have illuminated some dark places, and created shadows where false light shone before. The laboring epidemiologist, the statistician, laboratory director, and teacher of public health will find this charming volume a precious companion of their thoughts.

Paper, print, tables, graphs and references are worthy of the text.

HAVEN EMERSON

Medical Entomology—By *Robert Matheson, Ph.D. Springfield, Ill.: Charles C. Thomas, 1932. 502 pp. Price, \$5.00.*

This volume is a scholarly presentation of the present known facts concerning the spread of disease by insects and their allies. It deals with the subject primarily from the entomologist's angle. The medical diagnosis and treatment are only touched on briefly, these being properly left to medical publications.

The text opens with a brief historical discussion on the Arthropods and human disease, followed by discussions on insects and their allies, the rôle of ticks and mites, the Hemiptera or true bugs, and the lice. The Diptera or flies and their allies are by far the most important carriers of disease, and 10 of the 20 chapters are devoted to them. Of the Diptera, the mosquitoes are the most important disease carriers and special consideration is given to them, their identification, and means used to keep them under control. Besides the

mosquitoes, the Psychodidae, the Tabanidae, the blood-sucking nemoceros and muscoidean flies, and the house fly are considered as carriers of human diseases. A chapter is devoted to Myiasis, one to the rôle of fleas in the spread of disease, and one chapter to poisonous biting, stinging, nettling, and blistering insects and allied Arthropods. The final chapter is devoted to the collecting, rearing and mounting of insects for study.

A feature of the text is the tables and keys for identifying the various species of Arthropods considered. The illustrations are good, and while not numerous, are well selected. It was written as a textbook for classes in medical entomology, but the practitioner will also find it a valuable and an authoritative reference text. It is one of the best on the subject available, and up to date.

LEONARD HASEMAN

Manual of Bacteriology and Pathology for Nurses—By *Jay G. Roberts. (6th ed.) Philadelphia: Saunders, 1932. 259 pp. Price, \$2.00.*

As the title indicates, this is intended to be a textbook for student nurses. The section dealing with bacteriology reveals much evidence of inefficient revision. As an example, in some places streptococci are given as the cause of scarlet fever and in other places, this disease is classed with those of unknown causation.

However, such inconsistencies are slight as compared with some of the statements concerning bacteriological reactions and particularly those involving the subject of immunity. A few instances are too flagrant to overlook. The names applied to the various streptococci are confusing and certainly do not correspond with any logical nomenclature. It is hard to understand the author's division of bacteria on the basis of pus formation

as the reader would certainly conclude that this process was limited to the activities of the streptococci and staphylococci.

No mention is made of the occurrence of melitensis infection in the United States. It is unfortunate that typhoid vaccination is used as an example of the value of the opsonic index. Why should the plague bacillus be classed with the anaerobes when the organism is described as a facultative anaerobe?

Although the author prides himself upon presenting the latest material, the infective agent of yellow fever is stated to be *Leptospira icteroides*, and old terminology is used to describe the mosquito vector. Some little used methods for making the tuberculin test are described, but the Mantoux method is not even mentioned. Allergy and serum sickness are certainly not synonymous terms and should not be classed under the general title of "anaphylaxis," which term comes from the Greek and not from the German, as stated.

It might be possible to forgive many of the errors if the description of the Wassermann test was not so confused as to make it almost unrecognizable. On the other hand, most of the section on pathology is well written and quite correct. Even here, when the author reverts to bacteriological discussions, he is apt to slip. It would hardly be fair however, to leave the impression that the book is worthless. No such thing is intended. Much of the material is in such form that it can be readily assimilated by the elementary student. At the same time, it is hard to understand how so many errors can exist in 250 small pages.

JOSEPH A. KASPER

Magazine Publishing—By *Lenox R. Lohr*. Baltimore: *Williams & Wilkins*, 1932. 328 pp. Price, \$4.00.

Everyone who has the supervision of a publication, whether bulletin, pam-

phlet, or magazine, will find this a guide as to how to go about the myriad tasks which arise and which commonly have to be learned by experience or from that equally bitter teacher, the printer.

Mr. Lohr tells the editor how to manage his assistants, prepare his manuscripts and illustrations, and carries him through the whole process of deciding the most attractive and effective make-up and typography, besides introducing him to an intelligent comprehension of details of the printshop.

The chapter on editorial detail, including a page of proofreaders marks, will enable the editor to know and do what the printer expects of him. Mastery of its advice will insure good relations with those who must eventually carry every piece of printing to its final form in paper and ink. The book, though indexed, is not as well organized as it might be for grasping a desired bit of information instantly, but it does contain exact data regarding more of the innumerable tasks connected with publication than any other volume this reviewer has seen. FRANCES GRINSTEAD

Student's Handbook on Nursing Case Studies—By *Deborah MacLurg Jensen, R.N., B.S.* (2nd ed.) New York: *Macmillan*, 1932. 129 pp. Price, \$1.25.

The social phase of a patient's life is very often disregarded or little thought of in relation to his physical illness. Very often, as in the cases of some mental patients, the difficulty lies in their maladjustment to social conditions. In *Jensen's Student's Handbook on Nursing Case Studies*, the side of illness, its importance, its relation to the patient before entering and after leaving the hospital, are greatly emphasized and clarified in all types of cases.

This book is the only one of its kind published and should be in the hands of every nurse. RUTH ZINKAN, R.N.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Toxoid Replaces Toxin-Antitoxin—An announcement of unusual import comes from the New York City Department of Health: "Improvements made in the preparation of diphtheria toxoid," its bulletin says, "have led the Department of Health to discontinue the manufacture of toxin-antitoxin and to use toxoid in its place." Advice about dosage follows.

ANON. Toxoid Instead of Toxin-Antitoxin. *Weekly Bull.* 21, 48:377 (Dec. 3), 1932.

Rural Health Prospers—Despite the financial difficulties of the times, county health administration made in 1931 the best record of recent years—a net gain of 59 new county units.

ANON. Extent of Rural Health Service in the United States, 1928-1932. *Pub. Health Rep.* 47, 51:2299 (Dec. 16), 1932.

Aids Malaria Control—Two studies in Alabama confirm the proposal that plasmochin administered to a population will lessen malaria because it renders the human carrier non-infectious to mosquitoes. This ought to please the anti-vivisectionists. In all seriousness, it suggests that the use of the drug is a valuable addition to our present methods of malaria control.

BAKER, J. N. and GILL, D. G. Plasmochin in Malaria. *Pub. Health Rep.* 47, 49:2245 (Dec. 2), 1932.

Does Cancer Control Pay?—The Massachusetts cancer program is evaluated and found to pay real dividends on the sum invested by the state. Stimulating.

BIGELOW, G. H. and LOMBARD, H. L. Economics of the Massachusetts Cancer Program. *New Eng. J. Med.* 207, 22:972 (Dec. 1), 1932.

Random Thoughts on Milk-borne Sore Throat—Two definite conclusions

are arrived at in this rather discursive paper: One, that there is a great deal that we do not know about streptococcus infections. Two, that unless it is possible to apply rigid precautions against mastitis, the only safeguard against septic sore throat is pasteurization. To both conclusions we can all agree.

BROOKS, P. B. Epidemiology of Septic Sore Throat. *New York State J. Med.* 32, 23:1348 (Dec. 1), 1932.

Pneumonia and Heat—Steel workers whose jobs subject them to extremes of heat and humidity have markedly higher death rates from pneumonia than do general workers in the same industry. Preventive measures are proposed.

BRUNDAGE, D. K. and BLOOMFIELD, J. J. The Pneumonia Problem in the Steel Industry. *J. Prev. Med.* 14, 10:345 (Dec.), 1932.

Another Progress of Nutrition Report—This annual statement of the progress of research in nutrition is unusually complete, making it a mine of information for the casual student of the subject.

BURNETT, F. L. The Progress of Nutrition. *New Eng. J. Med.* 207, 33:1040 (Dec. 8), 1932.

Syphilis in Industry Again—Three articles on methods of providing medical treatment for syphilis among workers through various industrial health insurance or health service schemes.

CLARKE, W. *et al.* Syphilis An Industrial Problem. *J. Social Hyg.* 18, 9:481 (Dec.), 1932.

Does Age Lessen Industrial Value?—This Chicago study of reaction times stresses the industrial use-

fulness of the man over 40. Persons in the age group 40-59 had fewer accidents and less absenteeism on account of illness than younger men.

FISHER, H. E. Are We Old at Forty? *Indust. Med.* 1, 2:78 (Nov.), 1932.

Tonsils vs. Colds in Adults—

In a group of adults, some with and some without tonsils and adenoids, there was found to be no significant difference with respect to attacks of common colds between the two divisions.

GAFNER, W. M. Adeno-Tonsillectomy and Disease of the Upper Respiratory Tract (Common Cold) in Adults. *J. Infect. Dis.* 51, 3:489 (Nov.-Dec.), 1932.

Rights to Potable Water—Although this paper is a technical engineering and legal treatise, it succeeds in becoming a most interesting discussion of the use of potable water. It dwells largely with the celebrated Delaware River Case.

HORTON, R. E. Water Diversion Between Drainage Basins. *J. Am. W. W. Assn.* 24, 11:1623 (Nov.), 1932.

Citius, Altius, Fortius—About all that can be said concerning the value of physical education in its relation to general health culture and welfare here and abroad is said at its best in this extensive symposium.

LAPORTE *et al.* International Olympics Conference on Physical Education. *Physical Education Review* 3, 9:16 (Nov.), 1932.

Faulty Fixtures—Here are set forth the possibilities of contamination of water through faulty plumbing fixtures which permit siphonage through cross-connections and methods of testing.

MORRIS, S. B. Cross-Connections with Public Water Supplies. *J. Am. W. W. Assn.* 24, 11:1750 (Nov.), 1932.

More About Vaccination Methods—Smallpox vaccination by the intra-

dermal route is advocated after a four-year trial. The reactions are mild, and vesiculation and scarring were trivial or absent.

ROBERTS, B. E. Subcutaneous and Intradermal Smallpox Vaccination. *J. Prev. Med.* 6, 6:453 (Nov.), 1932.

Salmonella Poisoning—In this scholarly treatise on food poisoning, the author gives his reasons for assuming that the damage is done by undestroyed toxins produced by the salmonella group of organisms. He then gives the objections to this theory and ends with: "I have endeavored to deal impartially with this controversial subject, freely admitting that my views as to causation may be unsound, but giving you the reasons for the faith that is in me." Try to imagine an American writer closing his lecture with such an admission.

SAVAGE, W. G. Some Problems of Salmonella Food Poisoning. *J. Prev. Med.* 6, 6:425 (Nov.), 1932.

Bacterial Dissociation in Epidemiologic Studies —Do bacteria change in virulence by gradual adaptation during epidemics? The answer to this question will interest every epidemiologist. The paper must be studied to get any worth-while conclusion from it.

ZINSSER, H. and WILSON, E. B. Bacterial Dissociation and a Theory of the Rise and Decline of Epidemic Waves. *J. Prev. Med.* 6, 6:497 (Nov.), 1932.

Bacterial Causes (?) of Caries—Despite the fact that we are pretty sure about the dietary origins of dental caries, the bacteriological search for the cause goes merrily on. "*L. acidophilus* was found most frequently in the mouths of those children whose teeth contained three or more cavities." Hence some relationship appears to exist between the germs and cavities, concludes this author, even though he

reports the absence of the organism in many carious mouths, and its presence "rather frequently and consistently" in mouths without any dental caries.

TUCKER, W. H. The Possible Relation of Aciduric and Acidogenic Micro-Organisms to Dental Caries. *J. Infect. Dis.* 51, 3:444 (Nov.-Dec.), 1932.

Courts Sustain Milk Regulations
Reviewing twenty recent court decisions about milk, evidence is presented that courts uphold all reasonable regulations and licensing statutes. There is a reminder here that defective legislation may be the basis for trouble to come.

TOBEY, J. A. Recent Court Decisions on Milk Control. *Pub. Health Rep.* 47, 49:2250 (Dec. 2), 1932.

Medical Services for Mary Jones
—A skeptical medical profession is told how much the now famous program proposed by the Committee on Costs will do for the doctor's welfare. How the new and superior service will be rendered to Mary Jones is also set forth, but nothing is said about the method of inducing Mary Jones's father (and 25 million other fathers) to pay a rather high fee (\$36.00 per person) for services that may not be needed.

WILBUR, R. L. The High Points in the Recommendations of the Committee on the Costs of Medical Care. *New Eng. J. Med.* 207, 24:1073 (Dec.), 1932.

Respiratory Diseases Menace Childbirth—Despite surgical asepsis puerperal infections persist, the curve of incidence follows the incidence curve of respiratory infections at a somewhat later date.

WILLIAMS, J. T. The Relation of Respiratory Infections to Puerperal Infections. *J.A.M.A.* 99, 24:1992 (Dec. 10), 1932.

The Last Word About "Committee on Costs"—By far the ablest presentation of the proposals for socialized medicine. The problems are honestly and openly stated. For instance: if we are to invoke the insurance principle, we must guarantee the best medical care; provide the intimate service of the family physician, plus specialized aids: assure economy and efficiency. *Can we?* (Ed.) Although compulsory participation is the logical solution, the committee proposes experimenting with various voluntary schemes until the right way is found.

WINSLOW, C.-E. A. The Recommendations of the Committee on the Costs of Medical Care. *New Eng. J. Med.* 207, 25 (Dec.), 1932.

NEWS FROM THE FIELD

A.P.H.A. MEMBERS HONORED BY ROYAL SANITARY INSTITUTE

THE Royal Sanitary Institute of Great Britain has elected two of our members to Honorary Fellowship—George A. Soper and Mazýck P. Ravenel.

George Albert Soper is an engineer by profession, a graduate of the Rensselaer Polytechnic Institute. He received his M.A. and Ph.D. degrees from Columbia University. He has been a member of our Association since 1895 and is a Charter Fellow. He was the discoverer of "Typhoid Mary," the most famous carrier in medical history. He was the first to report an outbreak of influenza in the Army in 1918, in which he served as Major of the Sanitary Corps, and framed the 12 rules proposed by the Surgeon General and promulgated by President Wilson. From 1923 to 1929 he was Managing Director of the American Society for the Control of Cancer. For some years past his attention has been directed particularly to street cleaning and the disposal of garbage. He is Chairman of a joint Committee of the American Society of Civil Engineers to investigate the subject and to promote education in regard to it. He has taken interest in many civic affairs, and has had many positions of great credit and honor. He was engineer in charge of rehabilitation after the terrible storm in Galveston in 1900, and studied the epidemic of typhoid fever in Ithaca, N. Y. in 1904. He has also investigated the subway air in New York, and served as President and Director of scientific work of the Metropolitan Sewerage Commission.

Mazýck P. Ravenel, M.D., has been a member of our Association since 1899 and is a Charter Fellow. He retired

from the practice of medicine in 1893 and has since been connected with teaching and research work at the University of Pennsylvania, the University of Wisconsin, and the University of Missouri. He was the first bacteriologist of the State Live Stock Sanitary Board of Pennsylvania, and conducted the experiments which proved the danger of bovine tuberculosis to human beings. He was President of our Association in 1920-1921, and in conjunction with Henry F. Vaughan, took over the editorship of the JOURNAL in January, 1922, became Chairman of the Editorial Committee, December, 1924, and Editor-in-Chief in March, 1930, a position which he continues to hold.

The Royal Sanitary Institute has honored other members of our Association in the past in a similar way. We appreciate its action at the present time, and feel sure that it will further cement the very cordial relations which have existed between our Society and the Royal Sanitary Institute.

CLEANLINESS INSTITUTE

CLEANLINESS Institute has arranged with the National Tuberculosis Association for the distribution of the educational materials created by the Institute for public use, through the association's state and local branches and affiliates. On account of a drastic reduction in the budget for its educational services in 1933, the Institute has been obliged to discontinue its own distribution of these booklets, school readers, posters, etc.

The transfer of this material from the headquarters of the Institute at 45 East 17th Street, New York, to the various state tuberculosis associations should be completed by February 25.

Health officials, schools, writers, industrial executives, public health nurses and others, may obtain this material from the association in their own state after this date. Hereafter, all requests for publications received by the Institute will be referred to the National Tuberculosis Association or to the appropriate state association.

The curtailment of the Institute's educational service has required also the discontinuance of the staff heretofore associated with this work. Under these circumstances, Roscoe C. Edlund, the general director, announces that the Institute cannot continue extensive correspondence, field service and detailed assistance, but that he will be glad to serve as far as possible in continuing Institute contacts. Mr. Edlund requests that all correspondence be addressed either to him or to Cleanliness Institute.

PSITTACOSIS

THE discovery that native birds of the psittacine family in California now harbor the disease "psittacosis," and that it is therefore no longer solely an importation was made by the California Department of Public Health under the direction of Dr. Karl F. Meyer, Director of the Hooper Foundation for Medical Research, San Francisco. Research into the prevalence, transmissibility, the carrier state in birds, and possibility of infection in birds other than psittacines, is now going on in the Hooper Foundation Laboratories.

PUBLIC HEALTH SURVEY

A SURVEY of public health work in Delaware County, Pa., will shortly be begun by Dr. Joseph W. Mountin, F.A.P.H.A., of the U. S. Public Health Service, through the coöperation of the county medical society, the county tuberculosis association, and other health and civic agencies. It will be the aim of

the survey to obtain accurate information on all health activities of the county, to formulate effective methods for preventing and combating epidemics, to coördinate the work of agencies in the health field, and to prevent and correct overlapping and waste of effort.

NEW MILWAUKEE HEALTH CENTER

THE Matthew Keenan Memorial Health Center, a gift to the city of Milwaukee by the late Matthew Keenan, was opened recently. The cost was \$150,000.

NATIONAL CANNERS ASSOCIATION CONVENTION

THE Twenty-Sixth Annual Convention of the National Canners Association, the Canning Machinery and Supplies Association, and the National Food Brokers Association was held in Chicago January 23-27.

PERSONALS

JAMES H. ELSON, who retired 10 years ago as Chief Inspector of the Health Department in Jamaica, Queens, New York, died December 1. He spent 20 years in the Health Department, starting as an inspector of the Bureau of Sanitation.

DR. OGILVIA C. RICKSECKER, of Wilmet, was appointed Health Officer of Stark County, Ohio, to take office January 1. He succeeds Dr. Floyd R. Stamp, of Alliance.

JOHN W. BROWN, M.D., member A.P.H.A., who has been Health Officer of El Paso for 5 years, is the new State Health Officer of Texas. He succeeds Dr. J. C. Anderson, F.A.P.H.A.

DR. P. HERNANDEZ LIRA, member A.P.H.A. has been appointed Director of the Training Station for Public Health Workers, sponsored by the Mexican Public Health Service and the Rockefeller Foundation.

DEATH

DR. LOUIS CANTOR, member A.P.H.A. since 1928, died January 10 in Jerusalem. He was chief sanitary engineer of the Palestine Government. Dr. Cantor was born in Syracuse, N. Y., gained his first engineering experience at the Panama Canal under General Goethals, and subsequently was an engineer for the City of New York. In 1918 he went to Palestine with the first contingent of the Hadassah medical unit and was placed in charge of the anti-malaria campaign there. He was 48 years of age.

CONFERENCES

February 6-10, American College of Physicians, Seventeenth Annual Clinical Session, Montreal.

February 13, 14, Annual Congress of the Council on Medical Education and Hospitals of the American Medical Association, Chicago, Ill.

March 21-25, Fourth Pan-American Medical Congress, Dallas, Tex.

April, American Physiological Society, Cincinnati, Ohio.

April 3-8, New York Food and Health Exposition, Grand Central Palace, New York, N. Y.

April 4-6, American Water Works Association, Southeastern Section, Albany, Ga.

May 29-31, Western Branch A.P.H.A., Pasadena, Calif.

June, State and Provincial Health Authorities of North America, Washington, D. C.

June, State and Territorial Health Officers Conference, Washington, D. C.

June 11-17, National Conference of Social Work, Detroit, Mich.

June 12-17, American Medical Association, Milwaukee, Wis.

June 26-30, National Tuberculosis Association, Toronto, Canada.

July 1-7, National Education Association, Chicago.

July 5-9, International Union of the Protection of Childhood, Paris.

July 18-20, International Congress of Pediatrics, London.

July 10-15, International Council of Nurses, Paris, July 10-12; Brussels, July 13-15.

July 25-29, British Medical Association, Dublin.

July 29-August 4, World Federation of Education Associations, Dublin.

One year ago an investigation of the so-called Vice-squad in New York City created a wave of public indignation. Legislation was enacted so promptly to reform the situation that Mr. Waterman, who was about to publish the results of an extensive investigation which he personally had carried on, had to revise his findings entirely in order to bring his report up to date. The product of his labor is now ready, entitled "Prostitution and Its Repression in New York City (1900-1931)." The work should be of value to individuals and organizations interested in dealing constructively with the problem of prostitution elimination. Published by Columbia University Press, price, \$3.00.

The American Journal of Nursing

It is not only the nurse executive or the nurse instructor who finds the *Journal* a welcome daily guide. The humblest, the most isolated, private duty or public health nurse loves it and uses it. We know, because she tells us.

Mental Health of the Preschool Child*

IRA S. WILE, M.D., F.A.P.H.A.

Mount Sinai Hospital, New York, N. Y.

ABOUT half of the hospital beds in the United States are utilized by victims of mental and nervous diseases. It has been estimated that approximately $4\frac{1}{2}$ per cent of the total population of the United States will, some day, be in a hospital for mental diseases. The State of New York sustains an economic loss of \$130,000,000 annually as a result of mental disease.

Without tabulating the numbers of mental defectives, epileptics, neurotics, and psychotics, it is patent that the mental health of a community should play a definite part in any public health program although, up to the present, it has received comparatively little attention from public health officials or in the AMERICAN JOURNAL OF PUBLIC HEALTH.

For too many years health has been regarded as a term relating only to physical well-being. In its broad connotation, however, health is more than a state of optimum activity of the physical organization of man. It is rather a state of well-being that enables him to live most and best and to realize his functional potentials. Men-

tal health is part of the unity of life and it involves a consideration of the welfare of people in terms of their satisfactions, their services, and their human relationships.

Mental health at all periods of life represents the healthful operation of mind. It encompasses the subjective side of life. Mere existence is valueless; consciousness of existence determines whether or not life is worth while. Preschool age children are as much concerned with their own subjective reactions as any other members of the community, even though they may not possess an understanding of their own potentials or realize the meaning of social adaptation. Whatever is to be done in the realm of preventing mental disease, whether by public enactment or private efforts, it is obvious that infancy and early childhood afford the richest opportunities for constructive service.

The public health movement is concerned primarily with the field of prevention. In so far as various diseases play a part in diminishing the mental health of children, the psychiatrist is in harmony with all efforts to diminish those diseases which lower the physical vigor of the communities and undermine the mental stability of their citizenry.

* Read at a Special Session on Mental Hygiene of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

No therapist would deny the tremendous mental factor existent in treating various patients suffering from tuberculosis, syphilis or orthopedic deficiencies. No one could gainsay that all public health efforts to control tuberculosis and syphilis, rachitis, diphtheria, poliomyelitis, and other diseases in infancy, safeguard mental activity as well as physical soundness. Everyone will concede the physical and psychical significance involved in the prevention, palliation, and cure of sensory and motor handicaps, whether strabismus, epispadias, or webbed fingers; whether an intra-uterine amputation, a congenital cataract, or an ophthalmia neonatorum. Body and mind—there is mind in body and body in mind. The mental health of the preschool child, therefore, involves at every level the preservation of his physical well-being, as a primary factor in establishing the potentials of normal psychical living.

The preschool child occupies a temporal position between infancy and school attendance. But the line on either side delimiting his status is not sharply drawn. His mental health involves the events preceding the age of 2 years and the shadow of the events which are to occur at the age of 5 or 6 years. The psychic well-being of the preschool age child is bound up in such problems as are concerned with the prenatal care, maternal mortality, rational spacing of pregnancies, adequate obstetric attention, and a lessened use of forceps, especially among primipara. Convulsions and mental retardations involve work, not merely with cripples, but with immense problems of psychic rehabilitation in order to secure a reasonable adjustment to our rapidly moving life. It is obvious that mental health is not a thing completely apart from physical well-being. The child with a brachial paralysis, a hemiplegia, or a traumatic strabismus, is a sufferer

in toto as well as *in loco*. The treatment of the injury is a thing apart from the treatment of the injured, and both are interwoven with mental hygiene.

The fact of birth itself is a psychophysical factor, in so far as it subjects the child to physical strains and cerebral pressures, and it may occur in a psychological atmosphere which may be disadvantageous from many angles. The death of a mother in childbirth alters the status of the potential mental life of the child. The maintenance of family life or the presentation of an adequate substitute, therefore, plays a part in fostering mental health. I am not interested at this particular moment in discussing the very important familial limitation of offspring with reference to the mental health of children. But it is fair to remark that many of the mental maladjustments of preschool age children arise from their psychological reactions at being unwanted, neglected, or abused for reasons not understood by themselves, but which play a part in the emotional atmosphere of the home into which they have been born. Some children are actually penalized by their own birth, and they react with forms of aggressive behavior not dissimilar in kind to those exhibited by their noisy elders when thoroughly conscious of their own rejection.

It is manifest that an intelligent home and an educated parenthood offer far better background for the development of mental health than a home of ignorance, brutality, instability, and disorganization. Frequently tantrums, enuresis, night terrors, somnambulism, excessive lachrymation, restlessness, irritability, whining, and sulkiness are symptomatic of home activities or inactivities out of harmony with rational child training.

The preschool age is of the utmost significance because it is the period of life when the main mechanisms evolve which are concerned with human de-

velopment. It is the period of neurological life during which myelinization occurs, permitting the organization of new associations, the limitation and direction of capacities, the acquisition of experience, and the development of character trends. Mental deficiencies become more evident and their management by medicaments or education calls for diagnostic judgment and therapeutic guidance. The early detection of potential school retardates, institutional types and economic ineffectives, enables society to provide the intelligent care and resourceful training that advances the mental health of the children and protects the later social welfare of the community.

Primarily the preschool age is one of personality expansion, or, one might even say, the period of personality cohesion. Consider the evolution of locomotion, speech, manual activity, emotional experience, and social intercourse, and their mutual interactions as well as their interplay in the personality in the making. All of these developmental functions play a part in laying the fundamentals of mental health of the preschool child.

First, in order of importance, I should lay stress upon the age of habit formation. There enters into mental health the factor of habituation whether to one's own visceral activities, to one's own ego, or to social life about him. Hence mental health is manifest in the development of adequate and acceptable habits with reference to food, to the excretions, to sleep, and to the genital areas. If one thinks of anorexia nervosa, enuresis, pavor nocturnus, and masturbation, one immediately senses a disturbance of psychic equilibrium. Such habit reactions give evidence of incomplete adjustments to life. Underlying difficulties may inhere in faulty training by parents, in an action of revenge, or in a response to a feeling of fear, or to some insecurity arising from

parental, mainly maternal, indifference or ignorance. The development, therefore, of intelligent parenthood with reference to basic habits possesses fundamental values. Public health functions best through education. Knowledge concerning correct habits and the hazards of somatic irregularities is more useful socially than information concerning vitamins, or poliomyelitis, sera, or the treatment of chronic arthritis. The prevention of a phobia, a revenge motive, a sense of personal inadequacy, may lessen the future prevalence of neuroses, psychoses, delinquency, and crime.

The preschool age should be regarded from its developmental angle. I need but call attention to the variety of experiences which play a part in the evolution of personality. The development of locomotive stability, the necessity for visceral balance, the significance of nutritional equilibrium with an adequate amount of vitamins and minerals in the dietary, the growth of endocrine harmony, the natural development of hand preference, the active immunization against infections, protection against traumatism, all play a part in safeguarding not merely limbs and viscera but in determining the mode of life which the child is to enjoy and to which he is to react. The originally left-handed child who is forced during this period to become right-handed later may evidence his disability in stuttering and may find himself further penalized psychically by an increasing speech difficulty and his growing fear of his own limitation. Thyroid and pituitary disturbances manifesting their influences upon body growth and mental activity may become the basis of incapacities subversive of normal mental function. The public health representatives have unusual opportunity for locating preschool age children with developmental difficulties and in inaugurating a program for their welfare.

While I have mentioned both habit formation and developmental difficulties from the mental standpoint, this pre-school era of psychic reaction is of transcendent importance. This is the age of developing speech, of interchanging ideas, of testing out one's universe, of experimenting with the environment, of exercising the pioneer trait of curiosity and seeking satisfaction from and for it. This is a period during which, to a large extent, the interests of the child and the adult are not identical because their worlds are not identical. It is the age for the child to discover his own ego and to find himself as an individual—a person and an individuality—working in a world dominated for the most part by creatures of a larger growth. These, including parents, relatives, and other well wishers, desire to guide him and bring into his life the “musts” and “don’ts” that are so often in conflict with his desires and purposes. From the combination arises an assortment of conflicts, some light, some heavy, some superficial, some deep, some conscious, and some finding their habitat in sub-consciousness. They may emerge as tantrums, cruelty, tics or hysteric behavior, maladjustment, exaggerated activities, and neurotic reactions.

Fundamentally, however, mental health is not a matter of anatomy, nor is it primarily a matter of intellectual endowment. It is rather one of reactivity and reaction to a universe in terms of feeling. I shall omit reference to hereditary traits in neuropathic, defective, and originally diseased families, and consequent mentally dysgenic familial pressures, save to note that the locating of such families is a reasonable public health function in the interest of a program to foster the mental health of a growing generation.

The preschool age affords an abundant opportunity for the evolution of emotional trends. In self-occupation,

in efforts to secure independence, in contactual experience with brothers and sisters, parents, nurses, and the world at large, the child finds the agreeable and disagreeable. It is not necessarily a pleasure and pain alternative, but nonetheless there is a definite unfolding of some basic emotional mechanisms. His personality has to depend in a large measure upon the fundamental bonds of his primitive emotional life. Phylogenetically, emotional and reflex action antedate intellectual and purposeful activity. If one considers merely such reactions as appear during fear, he appreciates that the over-development of fears during this period of life leads to a contraction of the ego. While rage may lead to ego expansion and aggressive activity, the inculcation of fears and the temporary experience of incipient states of terror rob personality of its security and diminish the stability of the self. Fear devastates the spirit within and may show comparatively few effects to those round about; rage may dissipate its energy upon those round about and leave but a small trace of its damage upon the being within. Fear is more directed at one's own self, while rage expends itself more upon others. Love and hatred as positives and negatives, find themselves bound up with fear and rage in determining the nature and extent of mental health during this early period of personality formation.

The emotional unfoldings together with the conscious recognition of one's own capacity to evidence emotions, combined with reactions to the emotions of those about one, involve social experiences of all kinds.

Preschool life involves almost the maximum contact of parents and siblings. Most of it grows out of the home itself although much is found in the interactivities of recreational life. There enter likewise the beginnings of self-selection of friends and playmates, the sensing of likes and dislikes, the

attitudes toward games and sports, the selection of interests and occupations. In addition, special contacts occur with doctors and nurses, public health workers, social workers, teachers in nursery schools, as well as parents, grandparents, relatives, boarders, friends, visitors, and workers about the home.

Vaccination, immunization, an enema, irrigation of the ears, colic, a blister, a tonsillectomy are physical events with subjective values but they are less important than what happens to the child under conditions of discomfort and distress. The fact is equally true for rewards and punishments at all ages. No contact is devoid of experiential value. No experience can be wholly negative in character. Whatever happens is a stimulus to which the child must respond. He is conditioned by the world into which he is received, as well as by the parents who have passed on to him certain hereditary determinants. His life, therefore, is dynamic. He is essentially labile; and inactivity during this age places him upon a vegetative rather than upon an animalistic level. He lacks the independence of the young animal but he has the advantage of associative memory, multiple choice, and a capacity for changing interests and enthusiasms. His mental health involves constant adjustment and adaptation. He is continuously testing his power and worth in terms of his limited but increasing ability to cope with life. His home is an island which gives him reasonable security, but he would cross the strait and start an adventure on the main land of life.

Much of what the school child is to be depends upon these early interactions. How far is maternal overprotection to harass him, lessen his confidence, and sap his psychic independence? To what extent are false parental attitudes to hamper his natural development? To what extent is he to

be merely an instrument for parental pleasure, parental satisfaction, or for parental expiation? To what extent is he to be in competition, always compared with someone else to make him feel his limitation, his inadequacies, his inferiorities? To what extent is he to be penalized by a lack of opportunity, by vicious patterns, by cruelty, by personal abuse, and by witnessing marital infelicities? To what extent is he to be the victim of misunderstanding and repression? To what extent is he to be the victim of parental fears, disappointments, and vicissitudes? Is he to be merely a toy, an outlet for parental emotions, a comfort and solace, a satisfying but spoiled object of manifold solicitude? How far indeed is he to be regarded as a person rather than a thing, an organic being rather than an object in the house? Such questions are vital in considering his responses, his habits of mind and thought, and his behavior reactions. They are to affect his character, his health and his happiness.

Mental health involves the cultivation of a few fundamental principles and practices. Personality as a unit consists of the interaction of numerous trends. The estimation of what constitutes mental health is a matter of social opinion. Majority opinion constitutes normality. The norm of mental health involves a reasonably broad band of activities which do not pass beyond those vague limits which are held to be the beginning of behavior detrimental to others. These standards vary in communities, and even within communities according to accepted levels of behavior of families. Lying would be regarded by one family as an evidence of mental ill health and by another as natural, normal, and expected. In one group stealing would represent a fearful and fear instilling state of mental disease, whereas in another it would be deemed part of

experience, reasonably common and without a hint of mental deterioration.

Strangely, most forms of behavior which are aggressive in character and represent a profound effort to grapple with life's situations are held to be more pernicious than the tendencies to sit apart, to be quiet, self-amusing and hesitant, if not absolutely shy with others. A balance between extravert and introvert trends obviously is more advantageous than an extreme expression of either one of these personality trends. The experience of child guidance clinics amply illustrates that parents regard as evidence of ill health those characteristics which, for the most part, interfere with parental comfort and the generally desired peace standards of the household.

Every form of behavior must be regarded as purely symptomatic, as representing the activity of the total biologic social organism. One should not consider the mental health of the preschool child with a segregated reference to his physical well-being, or his intellectual potentials or his emotional trends or his social relations. It is the totality of these which enters into his thinking and doing, into his reactions toward what he wishes and what he wills to do, as well as into his positive or negative attitudes toward the desires and demands of those round about him.

One sees very little of epilepsy, and still less of psychoses among preschool children. Mental deficiencies vary in degree at this age, whether they are congenital, acquired as a result of birth traumata, or due to the dwarfing or warping of the personality during this primary period of development. The emotional conflicts and struggles which are incidental to youthful experience are part of the trial and error experiment that is determining capacity to adjust to both success and failure in life. This is a period of adjustment not for school life but for all life. In it are laid those

foundations whose values will be determined while grappling with the intellectual life of schools and experiencing the emotional life of adolescent love affairs, as well as in revealing their capabilities for adult adaptation. Mental health, therefore, calls for primary consideration, not in terms of psychoses, even though some of the seeds of psychotic conditions may be planted during these early years, but in terms of constructive factors that integrate the personality.

The preschool child who is allowed to cultivate his independence, who is encouraged in attention, persistence and coördination; who is aided in the establishment of habits of order and regularity in function; who is given an opportunity to play and to share with other children; who is given a variety of helpful parental patterns; has the finest opportunity for building up normality in mental health to the time of school entrance.

The preschool child must not be regarded as an isolated individual. His mental health is a continuum, probably extending from the moment of conception until the time of physical dissolution. A single age period has been set off arbitrarily as representing the period of the preschool age. One merely glimpses at this period of 4 years and finds that it is a period of rapid change. It is an age during which his physical growth is not marked by great increases in height or weight. Between the ages of 2 and 6 years he gains little more size or pounds than between the date of birth and two years but his psychic growth, rapidly advancing, is transcendent in importance.

During the 6 years prior to school entrance the child learns more, acquires greater power, develops more mechanisms, and brings into harmony more strains of his personality than he will ever again organize in a similar period of time. Even bearing in mind the

tremendous new drives and emotional advances that are related to the development of the gonadal system during adolescence, one can safely say that the preschool period is the fundamental time for promoting mental health. It is a period of latent sexual pressures but is not without sexual influence in experiences. It is the natural age for establishing right habits of action and of reaction; for promoting social friendliness with a full consciousness of one's own personality; and for fostering a sense of values in terms of adaptability and adjustment.

Preschool life affords ample bases for achievement, for meeting success and failure, for cultivating independence, for learning leadership, for promoting initiative, and for finding that wholesome balance between aggressive-

ness and submission which characterizes social adequacy. These are factors in, as well as functions of, mental health, whose foundations are to be laid in the preschool age before the social instrument of education with heavy hand endeavors to mould the plastic resourceful child to a single pattern of nonresistant, obedient, conforming childhood.

Public health officers can accomplish much by broadening their concept of health, by enlarging the scope of their protective and preventive activities so as to include within their dynamic functions the enrichment of life. This would be far more consequential to mankind than merely extending the expectation of life. To live is more than to exist and mental health is more than physical well-being.

Paper-Reading and Discussion

. . . The fact is, when people get to a certain age—not so great an age, either—they do not go anywhere to listen: they go to be critical and to talk: not to hear of the experiences of others, but to tell their own. For the young and the enthusiastic this is rather pitiful. It is so very hard to learn that the real secret of writing papers is not putting things in, but leaving things out. . . . The time occupied in impressing the extent of the erudition of the audience upon the audience should never on any account exceed 20 minutes at the very outside. Only the smallest amount of ground should be covered,

and the minimum number of ideas uncovered. Of these, only a few should be discussed at any length. To an audience the most attractive contents of a paper are those read into it by the audience. A set lecture is an entirely different thing, of course. The audience here is either prepared to concentrate for an hour or ready to endure boredom for that period. Speaking generally, a society meeting is no occasion for a lecture. A 20-minutes talk is what is wanted: unless, of course, one is a named contributor to a symposium, when 10 minutes should be the utmost limit.—*Pub. Health*, Jan., 1933, p. 130.

Are the "Nerves" and Badness of Childhood of Any Importance to the Field of Public Health?*

ESTHER L. RICHARDS, M.D., F.A.P.H.A.

Associate Professor of Psychiatry, Johns Hopkins Hospital, Baltimore, Md.

THERE are two reasons why I hesitate to use the phrase "mental health of childhood" before a group of physicians: First, the term mental health seems to make a distinction between health of mind and health of body; whereas in the reality of practice we cannot divide a human being into mind and body. We deal with health problems of individual child and adult as a total unit. Second, the term mental health is apt to carry commonly only one association—the intellectual development of child and adult, and this is a matter which public health physicians and doctors in general consider the business of departments of education. Suppose we discuss these two issues for a moment, and then pass on to some concrete examples of poor child health in the form of nerves and badness which the school child exhibits.

Health is an expression of the human being in action. While theoretically we may discuss the functioning of individual physiological systems of the body, we are quite aware that they do not exist in majestic isolation. The gastrointestinal system, for example, is so intimately associated with the cellular activity of the body as a whole that we cannot talk about digestion and metabolism and excretion except in

their relation to the total functioning of the organism. In like manner the structure and organization of the nervous system must be taken into consideration as much by the specialist in circulatory conditions, as the functioning of the circulation must ever be kept in mind by the neurologist. In short, a human being functions as an exquisitely integrated organism, every cell of which is dependent upon the behavior of every other cell. We know very little about the intricacies of these relationships.

In spite of the great advances in specific tests of a chemical, biological, and psychological nature, the reaction of the individual to the tests of life is still very much of a mystery. Why some people remain thin and others fat, some are bright and others stupid, some phlegmatic and others alert, in spite of heroic attempts at modification, are matters that intrigue us now as much as ever. We know that the constitutional endowment of a human being—intellectual, biological, temperamental—is a very definite and rather unmodifiable matter to deal with.

Only the youthful enthusiast wastes much energy in arguing whether it is environment or endowment that is the determinant of mental and physical activity. The rest of us prefer to adopt the more constructive approach of trying to find out what kind of environment and developmental assistance

* Read at a Special Session on Mental Hygiene of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

offers any given constitutional endowment its best chance of development. This is certainly the goal of preventive medicine, which has acquired a wealth of knowledge concerning the antecedents of malnutrition, bone deformities, heart disease, tuberculosis, and predatory bacterial enemies that lie in wait for childhood all along its journey. One has only to travel in other countries and see the toothlessness of young men and women to be consumed with admiration for the great work achieved in our own country in spreading the gospel of oral health alone.

It is because of the great results achieved by an intelligent campaign against the forces disorganizing biological growth and development that I am so eager to have preventive medicine include in its plans an equally concerted program against that seriously increasing menace of our national health—nerves. Nerves constitute a kind of poor health that we as physicians pay little attention to until it reaches the stage of hospitalization. Again and again we hear without concern statistics gathered from reliable sources which tell us that “nerves” called “neuroses” and “psycho-neuroses” constitute at least 50 per cent of cases coming to the specialist and general practitioner; that there are more patients in public and private psychiatric hospitals in this country than are found in beds occupied by patients suffering from all other disorders put together. Why have we ears but fail to hear the prophetic warning embodied in such statements? The reason is not complex. We are afraid of the whole topic of “nerves” because we do not know about this field.

Back in medical school the anatomy and histology of the nervous system is usually presented like a dose of catechism. With this bad taste of first and second year in his mouth, the third and fourth year student approaches his

clinical neurology with the profound hope that he may pass the course if he can memorize the last chapters of Osler's System in a more or less ritualistic manner.

Those who took part in training medical officers for service in the neuropsychiatric division of the A. E. F. were amazed at the ignorance shown by the average candidate with regard to making the simplest kind of neurological examination. And if such a condition exists concerning the fundamental principles of nervous system organization and structure, how great is the gloom when the physician is called to consider the psychological aspect of “nerves.” A dash of endocrinology, and focal infection theories, with a sprinkling of Jung and Freud completes the salad of words and not facts.

Nerves increasing under the pressure of our high powered civilization are being passed for treatment from the hands of pediatrician, general practitioner, and public health officer, to the jurisdiction of cults and sects and behavioristic academicians with the word “clinical” in front of their names. Now, there is nothing about the subject of nerves too deep for the grasp of any earnest and honest seeker after light. It is not necessary to read all the literature poured out on this field of health. If we wish to become intelligently aware of a few essential principles in other fields of medical science, we find time to take postgraduate work here and there, and to get a list of a few good books on the subject. The physician who works with children in private practice or in school health organizations has the greatest of all libraries and laboratories at his disposal—the school-room—if only he is interested enough to use it. Here is the place where one can see the nerves of the coming generation developing.

“Nerves” are in every instance a reaction to strain of one sort or another,

and their treatment must be directed toward modifying this strain. The symptoms of nerves in the school child cover a wide range of complaints many of which take us into the realm of what is ordinarily called conduct. Whenever a child annoys or disturbs his environment we think of his activity as conduct to be judged instead of behavior to be interpreted, and consequently focus our attention on trying to stop the conduct instead of trying to find out why he acts as he does. For example, here is a cross-section of complaints studied last year by a health officer in two of our Baltimore junior high schools. They are symptoms of strain manifested in 79 students of both sexes—

Easy tearfulness

Nervous stomach with occasional nausea and vomiting during school hours

Headache and dizzy spells

Impudence to teachers

Refusal to do homework

Irritability and grouchiness when criticized

Falling asleep in school

Laziness, inattentiveness, chronic truancy

Child complains of funny feelings in the head and says she cannot think.

Spells of saying queer things in school which she claims she does not remember afterwards

Child is unable to concentrate, flies off at the least thing, steals from her mother, is boy crazy.

Fits and screaming spells

This pupil is sullen and dull, has done well in school up to this year but now refuses to work.

Katie seems to be in a daze, goes to lavatory frequently, seems to have undue influence over younger classmates.

John is hopelessly slow in school, and does not follow directions.

May trembles and cries when called on in class, and says she feels sick all over.

Jane complains of weakness in her stomach and throat and has attacks of flushing in which she gasps for breath and says she is dying.

William has spent 4 terms in the 7th grade, now stays by himself a great deal to avoid teasing, is aggressively defiant towards teachers, is suspected of stealing but denies it with tears.

Here are complaints familiar to every teacher from kindergarten on, but she

usually does not mention them to the school physician because he is not interested in them. Moreover, if the physician examined such a child and found no physical defect, he would in all probability be as puzzled as the teacher.

The first step in studying the nature of the strain responsible for such symptomatology is to find out as much as possible about the stuff of which the child is made—intellectual, biological, temperamental. Fortunately psychology has put at our disposal in the group and individual intelligence tests and in educational tests a means of finding whether a child is adequately fitting the grade to which he is assigned. Discrepancy between intellectual ability and school programs and home expectations is one of the commonest sources of child nerves. A child who is forced to cope with a course of study beyond his ability will do one of two things, depending upon his temperament. If he is phlegmatic and easy-going he will quietly evade issues, play truant, hold up signing of report cards, and not infrequently drift into delinquency which is much more entertaining than the schoolroom. If he is sensitive, conscientious, timid, he will fret and worry over his failures to measure up, and not infrequently develop headache, nausea, fatigue, etc., as unwitting body protests against life as he is called upon to face it.

What can the school doctor do about situations like this? They are, to be sure, the job of departments of education. At least he can be so aware of the situation that he can place the facts of the strain frankly before teachers and parents that something may be done to lower standards and let up on the nagging. In large city schools intelligence tests are routine in the first grade, but frequently they are not repeated for several years on the supposition that the intelligence rating of early child-

hood will go on to adolescence. In rural schools there is frequently no intelligence testing, the teacher deciding in her own right whether a child can or cannot do his work. Then again there is the custom of promoting on trial, or advising summer school for children who have failed their grade. Too often this forcing is not so much the fault of the school as of parents who insist on son or daughter being promoted to satisfy family pride. The easing up of strain on such children may come through transfer to special class or opportunity class, or transfer to vocational or pre-vocational school. Or, if no such relief is available in a school system, removal of the child from school at the earliest possible moment the law allows with recommendation for work permit is far better for his mental health than continuance year after year in an environment saturated with failure and discouragement. In the 79 school misfits referred to it was found that the "nerves" of two-thirds of the group represented the strain of intellectual inability to meet school demands.

In studying the nature of a child's biological endowment the physician has many tests of science at his disposal, and yet perhaps his most valuable ally is a careful and painstaking study of empirical facts gathered from following groups of children on through adolescence. The best illustration of this fact is to be found in the data coming from the White House Conference on Child Health and Protection. When this body, consisting of 1,000 experts in every sphere of child welfare, pooled their findings after a year or two of work, one was surprised to realize the difficulty they had in agreeing upon such an apparently simple thing as what constitutes a state of nutrition.

We crave some quick and concrete method of standardization, especially in the biological field. As a matter of

fact the more thoroughly we go into that sphere, the greater individual variation appears, and the more complex becomes cellular relationships. We know from experience that certain types of structural organization stand strains of life poorly, and yet we cannot determine why. Childhood organizations, prone to tics and easy vomiting and asthma and eczema and persistent enuresis and night terrors and stammering, is human material that cannot put up a sturdy fight against handicaps of severe physical illness or intellectual strain, or a wealth of excitements and poor social conditions that another kind of constitutional endowment would not notice.

Pediatrics is studying these children with reference to finding means of desensitizing them when they are found to react to any one protein. It is an excellent point of approach provided that as physicians we also study ways and means of desensitizing these children to environmental situations that upset their emotional equilibrium. In such patients we almost invariably have restless, over-conscientious, often timid and extremely sensitive temperaments. We cannot make them over, but by recognizing their problems in early school years we can help them to learn to live with themselves better in years to come, and undoubtedly reduce their chances of being nervous breakdown liabilities.

Children with such neuropathic constitutions react poorly to speed tests, and competitive struggles of athletics or academic work with prizes and awards. Many of them are intellectually precocious, and find themselves the pride and joy of teachers who are eager to have them do extra work and skip a grade, or to add summer school to a school year that has already proved exhausting, or to push them into public speaking and school plays. The child himself shrinks from these things, but

goes on with the plans because he wants to please teachers and parents. It is impossible for the layman to distinguish between child reluctance born of a constitutionally unstable nervous endowment, and that associated with laziness or adolescent rebellion against life in general.

Such problems do not come to the school physician for decision until the child, bending beneath the strain of over stimulation, develops multiple tics, or functional choreiform movements, or stammering. Then the medical prescription is usually to take him out of school and make him rest as much as possible. What the child needs is not withdrawal from school, but easing up of the school load. Taking such a one out of school breaks up habit routine upon which he thrives, and focuses his attention upon himself as a weakling and nervous invalid—a concept that may stay with him all his life.

Another serious nervous handicap belonging in this group is stammering. Stammering may begin with the onset of speech in the preschool child, and in 9 cases out of 10 will disappear in a short time if the environment completely ignores the matter. It may begin suddenly in the school child or adolescent following a fright or other serious emotional upset, or it may come on gradually under a period of strain at home or in school. Often this type of stammering is accompanied by jerking and twitching and respiratory tics. Stammering is a condition that is usually treated with speech training by the department of special education. The objective of speech training is to teach the child a technic of coördination between breathing and articulation. The stammering child needs something more. He needs an understanding of the sources of strain from which his stammering arises, and he needs help in learning to manage his emotional life. Hand in hand with technics of

coördination must go a knowledge of this individual child and his home and school setting.

I have mentioned some of the general sources of nerves in the school child that pass unnoticed because of their frequent occurrence. To teacher and parents they are of interest chiefly because of their annoyance. To the physician they should be of interest because they are harbingers of poor health that he and his colleagues will be treating long after the school period is over. The child and adolescent well started in habits of nervous instability are as seriously handicapped for self support, and family formation, and wholesome civic relationships as if they were suffering from handicaps with lesional pathology.

We have in our educational and child welfare organizations the set-up for giving every school child the benefit of an all-round study of health conditions that affect him, but we cannot do this properly until there is more coördination between departments of health and departments of education. The doctor needs to have an intimate knowledge of the problems of the schoolroom, and the teacher needs to have a larger concept of health education than is now hers, and both doctor and teacher need more knowledge of the homes from which school children come.

Parent-teacher association is doing a good work, but it does not reach the individual child. Last winter when speaking at a Parent-Teacher Association meeting the principal said to me,

The mothers who need health talks most are not here tonight. We can never get them to take part in our meetings. We teachers have not time to visit them, and they never come to visit the school except to complain about something.

One cannot expect our over-worked school nurses to get social data in their hurried visits. Here is the function of the visiting teacher—to acquaint school

with home and home with school. Years ago when teachers boarded around and there were family doctors, the community was acquainted. Today under the complexities of modern living all is changed to a status of mass production in health, in education, in social relationships. We cannot change these conditions, but we can work out some coördinated plan by virtue of which health problems of the individual child are not lost sight of in our ministration to the group.

The children handicapped by motor disability, defective vision, hearing, speech, and intellectual retardation are the educational problem of departments of special education in which psychologists and teachers expert in the pedagogy of specific handicaps plan and work with them. Except for examination of the specific physical disability, the school doctor has no contact with these children so far as interest and inquiry into the way they are adjusting themselves to these limitations is concerned. He could learn a great deal if he knew them better.

The futile struggle to adapt one's self to a world cut off by the elimination of a special sense organ, or the ability to achieve locomotion, reacts on the personality of the handicapped in a great variety of ways, depending on his temperament—whether he is ingrowing or out-going—and upon the opportunities which environment offers for self-expression. A wholesome start in the childhood of these human beings determines the trend of their entire lives.

The teacher cannot do it all. She needs the interest and intelligent helpfulness of the physician who has a concept of health that is not limited to the technics associated with his particular specialty. Public health cannot afford to ignore the behavioristic aspects of its field of service. The burden of its neglected opportunities falls back

inevitably upon nation, state, city, and rural community in the form of chronic dependence, state hospitalization, organizations for dependent and neglected childhood, penal and correctional institutions; yet schools of public health and hygiene have practically no place for the study of mental hygiene in their curricula.

As lay and professional people we have always been keenly interested in the welfare of children, but our interest has been more or less desultory and uncoördinated. It has been an interest more philanthropic and religious, than an interest associated with any scientific inquiry into the nature and needs of childhood. The dependent and semi-dependent child we have thought of as needing food, shelter, and clothing, and a certain amount of "schooling," but we have paid comparatively little attention to the best interests of these children as individual boys and girls.

Year by year medicine and education, and the behavioristic sciences of psychology and psychiatry have been driving home to us the fact that the mental, physical, and social health of the adult life of every community must begin with an intelligent and constructive interest in the story of the individual child.

Child-caring organizations are drawing away from the institution as a unit of ministration to the dependent child, and declaring themselves in favor of the boarding and foster home. The family is after all the basic factor of community life, and the child who does not grow up with the consciousness of being a part of a family group misses something that institutional life cannot supply. Hence modern social science is spending a great deal of time, money, and thought in keeping families and homes intact, and in trying to study the social, economic, and health forces which tend to undermine the stability of the home. Here are matters that come within the

Mental Hygiene of Adolescence*

WILLIAM A. WHITE, M.D.

President, Institute of Mental Hygiene, Washington, D. C.

THE subject upon which I am asked to speak does not necessarily serve to confine me to the limits that would ordinarily be indicated by the title of my paper. When I was asked to talk to you on the subject of the Mental Hygiene of Adolescence certain things suggested themselves to me which I conceive to be of importance and those are the matters which I shall discuss.

In the first place, I think I state a generally recognized truth when I say that adolescence is a period of especial stress. This is because it is a time when the instinctive tendencies assert themselves very strongly and at a time when the individual is expected to conform to the social conventions. As a matter of fact, he has had very inadequate experience. He has not accumulated wisdom, and he has not had the time to acquire self-control; so he is faced with the necessity of conforming when it is pretty apt to be beyond his powers to do so. I am sure that this state of affairs must be pretty generally known, and yet it is never taken into consideration, at least by the law.

A very large proportion of delinquencies occur at this time, and a not inconsiderable number of very serious crimes are committed. Homicides are by no means infrequent, and I am sure that prison wardens would tell you that this is the period when serious crimes are most apt to be committed, and when men and women first enter upon their

criminal careers. A judge who told me that he had just sentenced a 14-year-old boy to be hanged for murder, and went on to explain that the boy knew the difference between right and wrong and that was all there was to it, illustrates in a rather tragic way the total lack of understanding which so frequently faces the young adolescent when he gets into trouble.

The difficulties of the adolescent, whether they be delinquencies or mental illnesses, cannot be understood without appreciating the undue burden of instinctive urges with which he has to cope at his period of life. We can therefore think of him in terms of these instinctive tendencies and his capacities for dealing with them in accordance with accepted standards of conduct. Either his instinctive tendencies are too strong or his self-control is too weak, or both, when he gets into trouble.

But let me interject at this point a suggestion which I think is always helpful in understanding these situations. A boy whose instinctive tendencies are not strong enough when he is an adolescent to get him into more or less mischief is a boy whose equipment for life is lacking in the necessary energy to carry him very far; or, to put the thing a little differently, the goody-goody boy, the boy who never makes any trouble, who has all of the virtues and none of the vices, is pretty apt to be fundamentally a weakling. I inject this comment because I think it is of significance and importance, and because I believe many a boy is wholly misunderstood because this matter of

* Read at a Special Session on Mental Hygiene of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

energy equipment is not appreciated, and then, again, I have injected it because I believe that such a concept makes for greater tolerance as well as understanding of adolescent delinquencies; and helps the adult who has to deal with them to that frame of mind which sees the situation in its true light and enables him to guide the youth rather than use methods so frequently employed which are destructive.

All of this, you see, naturally leads to the inevitable conclusion that the adolescent's assets and liabilities are conditioned by what has happened to him in his bringing-up during the previous years. In other words, a successful adolescence is dependent upon adequate care and training in early childhood; and so at this point I wish to say a few things about the care and training and bringing-up of children which I conceive to be of fundamental importance in this whole question. The present century has been called the century of the child; but very often, I fear, with little appreciation of what a short distance we have come from the crudities and cruelties of the past, and of how much we are still involved in the same emotions that gave rise to them and in ignorance and indifference and selfishness toward the new generation. Many historical facts might be mentioned but I merely wish to call attention to what is common knowledge --that these cruelties of the past were largely practised on the theory that the parents owned the child and therefore he could be sold into slavery or be killed, as suited the parents' convenience.

As you know, China for hundreds of years was the country where infanticide was practised on a large scale; especially the female children being drowned. Edicts from time to time were published against this practice, and in the reign of Koang Sui, which began in 1875--only yesterday--these efforts were con-

tinued. But enough for the past. What is the condition at present? I have before me the figures of the National Child Labor Committee, which give a total of over 2 million children under 17 years of age employed throughout the United States in gainful occupations. Some of them are only 10 years old. It is economic pressure which has brought to the fore conditions which we never believed could have existed in this country, and at the same time has emphasized qualities in human beings which we thought, or perhaps only hoped, had been eradicated by civilization.

The high point for the child in the 20th century was President Hoover's White House Conference on Child Health and Protection. It will be noted in *The Children's Charter*, which was issued as a result of this Conference, that the child is entitled to full preparation for its birth. It goes on to state that his mother should receive prenatal, natal, and postnatal care, and that there should be such protective measures established as would make childbearing safer; but I think the first sentence, that the child is entitled to full preparation for its birth, means that the child should be wanted by the parents and that his birth should be arranged for on that basis. An enormous amount of the cruelty of the past was undoubtedly due to the birth of children who were not wanted. Particularly in China, the female child was a liability and was therefore killed, whereas in other places children became assets who could be put to labor, and made to help support the household. These conditions, of course, were most notable where the economic pressure was greatest.

If I were to sum up in a very few words all of the things which it is desirable that a child should have in order that he might emerge into a healthy adolescence, I would say that

he should have a feeling of security in a good home where he can be reasonably provided for, and that in addition to this, and perhaps still more important, the child should know without qualification that he is loved. These are the irreducible minima of healthy childhood; and yet if we will look about us only a little we will see how far we are from reaching such standards even in this so-called century of the child.

I will call your attention briefly to a few illustrations. In the first place, I think I can say without fear of contradiction that on the whole few children are provided for beforehand; that children come into the world more or less by chance and accident; that it is a rare thing for a parent to give as much care and thought to the planning for a child as he would to the planning for a garage, for example. I might go on to say, I think without fear of contradiction, that the child is also brought into the world for various ulterior motives. Not infrequently a wife decides to have a child thinking that thereby she will hold the loyalty and the affection of a husband whose interests are beginning to wander from the home. Whatever the result of such an experiment might or might not be, it is obviously not a fair procedure from the point of view of the welfare of the child.

Other such reasons may be cited, but I have before me a very interesting paper by Dr. Stevenson, of New York, a psychiatrist, by the way, who took the trouble to associate himself with a children's clinic, not in the capacity of a physician to the child but for the purpose of interviewing the mother and finding out why she brought the child to the clinic. It is exceedingly interesting to note that all sorts of reasons besides the health of the child were brought out. For example, one child was brought for the purpose of establishing a stronger case of neglect against the deserting husband by hav-

ing the physician say that the child was sick. In another case the child's aunt brought the child for examination in order to expose the neglect of its mother in caring for it by getting a diagnosis, the aunt hating the mother for taking away her brother's affection. In another instance the child was brought in order to prove its illness so as to avenge a dead sister by exposing her husband's neglect.

Such were the motives for which children were brought to consult the pediatrician; and I do not need to tell you that in all the work with children for the past quarter century we have almost invariably sought back of the child's illness in the home, and more specifically in the parents, for the cause of the trouble.

The child in the family is very much like a glass of milk in the ice chest, absorbing the flavor of all the personalities about him. Unfortunately, however, often this passive attitude does not sufficiently describe the situation, for the members of the household not infrequently use the child, as I have already indicated, as a means by which they can express their emotions, their animosities, their angers, etc.

You will see that I have wandered somewhat from my title but I wandered only in a direction which I intended to take. I have indicated that a healthy adolescence is dependent upon a healthy childhood, and then I have pointed out some of the defects in our modern attitude toward and understanding of childhood and children.

In setting forth the minimal requirements for healthy childhood I mentioned only 2—a good home and love. There is a third requirement which perhaps includes the other 2, and that is that the parents should be worthy objects of emulation for the child, that they should have personalities which the child can take over and idealize with the certainty that they will consti-

tute standards of conduct that will result in the building up of a healthy character and a good citizen. With all these requirements it is easy to see that we have the ideal setting for wholesome childhood, and this is the most certain assurance of a healthy adolescence. Of course, it is rather difficult to see how this last requirement can be brought to pass except as a result of many generations of development, but perhaps if only parents who wanted children had them a big step would be taken in this direction.

If the 20th century is properly called the century of the child, then it is only

because in this century the child has been discovered. We have not yet learned how to treat him, and, what is much more difficult, we have not learned that the parent needs the child as much as the child needs the parent. There is a mutual exchange in the parent-child relationship which is of the utmost importance, in my opinion, for civilization. It is only in the family relation, where sacrifices have to be made on account of children that those elements of altruism, sympathy, understanding, and tolerance are born which make the future of civilization worth struggling for.

DISCUSSION

CLARENCE M. HINCKS, M.D.,

General Director, National Committee for Mental Hygiene, New York, N. Y.

THE previous speakers have provided us with a rich nourishing bill-of-fare on the mental hygiene of childhood. I would like to congratulate those who are responsible for arranging this program in securing 3 outstanding psychiatrists who have contributed to the development of the mental sciences and who command our respect because they have gained valuable insight into the human nature of children through day in and day out intimate clinical contacts.

All 3 speakers emphasized the point that, for each stage of a child's development, there should be adequate previous preparation. Dr. Wile informed us that happenings before the age of 2 influence the preschool age period of 2 to 5; Dr. Richards suggests preschool age experiences as potent factors in determining later child development; and Dr. White reiterates the same philosophy in speaking on adolescence. This

seems to me to be one of the cardinal principles in the whole domain of mental hygiene—that the effective safeguarding of mental health consists in laying the foundation at each stage of life for the sake, not only of satisfactory adjustment during that particular stage, but as preparation for the next age range. It is because of this principle, for example, that we as health workers are concerned with the so-called patterns of reaction at the preschool age level, knowing that there are involved determinants for the direction of future personality growth. Indeed this principle carries through from birth to death. We are, for example, determining in our 40's, in considerable measure, the degree of our mental health in our 50's, and so on.

Dr. Richards's hesitation to utilize the term mental health because of the dangers to our thinking in the tendency to separate the mental from the physical

or the mind from the body is in line with common sense. The sooner we include in our conception of health what we have previously dealt with in a sectional way under physical health and mental health the better. A unified approach does more justice to the facts and facilitates more effective application.

And now, may I hazard a few observations concerning the relationship between mental hygiene and public health, and developments that are perhaps worthy of our support. I will be brief because I realize that it is not the function of a discussant to present a paper of his own.

In the first place, I would say that, unless mental hygiene becomes thoroughly integrated into public health philosophy and practice, it will not achieve its main objectives, and I have come to the conclusion that we who are identified with the so-called mental hygiene movement have been slow, not perhaps in realizing this need, but in formulating our experience so that it can be readily used by the rank and file of public health workers. What is requisite in this regard? We must approach the subject of mental health in a positive way. We must set forth, as far as our experience enables us, the conditions for healthy mental development. This has been done to a considerable degree in regard to physical health. In this realm the public health worker recognizes the importance of such positive measures or factors as fresh air, sunshine, a balanced diet, vitamins, exercise, and so on. The time has come when we must organize

our mental hygiene knowledge so that we can lay down something approaching definite measures that public health workers can understand, promote, and apply in their daily work.

As far as adults are concerned we are now in a position to indicate at least a dozen factors that are of vital importance in the preservation of mental health, such as, for example, occupation, recreation, suitable outlets for creative imagination, social intercourse, the gratification of ego urges in healthy ways, and so on. My confrere, Dr. George K. Pratt, has just written a booklet which I hope will be widely read by health workers, setting forth positive measures that are applicable particularly to those who have become victims of unemployment.

It is in the realm of childhood that public health workers can be most effective. Now that mental hygiene is sponsoring studies in child development and is beginning to discover the factors that lead to mental health on the one hand and to departures on the other, there is prospect of rich material for public health. The papers here presented are illuminating in this regard.

Before concluding, I would like to thank leaders in public health for the help they are giving in fostering sound developments in our field. During the last few years this coöperation has been magnificent. These leaders appreciate the fact that public health must be interested not alone in longevity but in the quality of life as well, and it is in this direction that mental hygiene has a potentially significant contribution.

The Aim and Accomplishments of a Health Center Mental Hygiene Program*

ELIZABETH I. ADAMSON, M.D.

*Consultant in Psychiatry, Bellevue-Yorkville Health Demonstration,
New York, N. Y.*

THE Bellevue-Yorkville Health Demonstration is financed by the Milbank Memorial Fund for the purpose of trying out approved methods for the prevention of disease and the promotion of health with more generous appropriations than are ordinarily at the command of public health authorities and private agencies. The district in which its activities are being carried on extends from 14th to 64th Streets on the east side of Manhattan, with Fourth Avenue as the western boundary below 42nd Street and Sixth Avenue above. The total population of the district is about 142,000. Dr. Shirley W. Wynne, Commissioner of Health of New York City, is Chairman of the Demonstration.

The nursing staff is composed of approximately 30 Health Department graduate nurses under the direction of the Bureau of Nursing of the New York City Department of Health, with which organization the Demonstration is not only coöperating and closely affiliated, but which also serves in the capacity of the official agency in the district.

The family case load of each nurse averages 300 while the individuals handled by each average 400. Besides dealing with the health problems of these families, the nurses are assigned

to the schools in the district and in this way are closely in touch with the school authorities and teachers of both the public and parochial school systems.

From April, 1929, to February, 1930, the Demonstration maintained a mental hygiene consultation service. This service was purely advisory; all problems needing intensive investigation and treatment were referred to mental hygiene clinics in the community. The staff consisted of one psychiatric social worker who functioned as part-time consultant.

In November, 1930, as an experimental undertaking, a complete mental hygiene unit was established as part of the Demonstration. This unit consists of a part-time psychiatrist, a part-time psychologist, and a full-time psychiatric social worker. The service is still largely for consultation, but now that more complete diagnostic facilities are available, treatment can be given to a few cases definitely needing psychiatric therapy. Assuming that this audience is especially interested in the educational aspects of the mental hygiene program, particularly as related to the nursing staff, we shall stress that aspect of the service rather than give the actual results of the clinic service, such as the number and type of patients treated, etc.

This is the first time that the City

* Read at a Special Session on Mental Hygiene of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

Health Department has embodied as part of its services a psychiatric unit, and, as such, it is an important demonstration in public health work. Besides believing in the advisability of demonstrating the need for a psychiatric clinic in a city health center, the directors of the Demonstration felt that more knowledge on the part of the nurses regarding personalities and their deviations would be a most useful adjunct in handling the other health problems as well as decreasing the incidence of mental and behavior difficulties in the district by early diagnosis and treatment. The experiment was more of an educational nature than that of offering clinic service to individuals, based upon the desire to attack mental illness by prophylactic measures.

This audience is only too cognizant of the fact that lack of knowledge engenders fear, particularly in preventive medicine. We are all too familiar with cases of pulmonary tuberculosis being diagnosed as "lung fever" and treated as such. A tragically high mortality resulted because no therapy is effective for a nonexistent, in other words wrongly diagnosed, malady. This make-believe disease was begot of primitive fear due to ignorance. For example, 10 years ago a confrère told me that he did not report his cases of active tuberculosis because he had to make a living, implying that the patients would seek another physician if he reported the illness. Gradually, through education, the morbidity and mortality rates of tuberculosis are decreasing steadily. Through education, the taboos have been removed from many abnormalities, and even with venereal disease marked strides are being made in the willingness on the individual's part to admit of an accurate diagnosis.

With mental illness, however, we are woefully lagging in this regard. One reason for this is that mental disease connotes to the layman legal in-

sanity. Naturally, no legally sane person wants to be considered insane; hence he avoids any admission of a term that smacks of insanity. Another impediment in the way along the road to a clearer understanding of mental disease is the social stigma attached to any form of so-called misbehavior. We are urged in our youth to approach perfection in some way and any inability along this line is viewed as antisocial, amoral or unethical. No one enjoys being labelled under any of these terms. There are numerous other causes why mental disease is a type that people fear most. Due to ignorance it is the pariah of medical pathology.

We, therefore, realized that an enlightenment of our population would most effectively be achieved by giving the nurses who served the people a clear understanding of mental hygiene principles. If the individuals in the community were to be reached the nurses would be among the ones to do it. Public health nurses are in a peculiarly intimate contact with their patients and because of this unique relationship can exert an immeasurable influence.

In my opinion, our nursing group of Bellevue-Yorkville, in their educational status and work efficiency, measure up to any similar group, yet they feel the need for more knowledge about the handling of personalities. Partly because of their making known this need, the directors were led to take the establishment of a clinic under advisement. The nurses have since realized more than ever that a mother's lack of coöperation in the administration of toxoid or in carrying out the doctor's recommendation concerning the baby's diet may be a mental hygiene problem. To give the nurses enough knowledge so that they could deal with personality deviations and through them to permeate the community with greater mental health was our main objective.

The question of method then presented itself. How were we to teach a group enough psychiatry so that they could recognize mental problems and be able to carry out certain types of treatment with the help of the mental hygiene staff? The methods chosen to achieve our aim were group discussions, not formal didactic lectures, individual conferences on cases referred to the clinic and personal interviews if they were desired. The individual conferences gave us a clearer view as to the efficiency and personality of each nurse, which in turn, was of great benefit in leading the group meetings. These latter were held twice a month, the first hour in the morning. The nurses were expected to attend the conferences and were excused from their other work for the hour unless a clinic was in session, in which case some few had to be on duty. Occasionally, for other personal reasons, a few nurses were excused from attending. Because of the desire to avoid rigidity and formality, the students were free to interrupt by discussion or questions. In this sense we cannot designate the conference as a lecture.

In all teaching there are certain essentials that the instructor must possess. The primary ones are a knowledge of the subject coupled with the sincere conviction in the soundness of this knowledge; a non-defensive and non-patronizing attitude to those whom he is to teach and above all an understanding and knowledge of the students at least collectively, preferably individually also. We shall not dwell upon the first of these; that can be readily determined by one's previous training and professional rating.

Regarding the attitude to the student body, what had to be coped with at the first meeting was the age-old defense of nurse to doctor. Even though it were in the scope of this paper we could not solve the problems of why the nurse

resents and yet is fearful of the supposed superiority of the person with an M.D. degree. At first they asked no questions and offered no ideas. They were dutiful, courteous, but silent listeners. They gave us the feeling that we were trying to impress them with profound and erudite ideas. Gradually, by individual conferences on cases that had attended clinic and whom the nurse was handling in the school or in the home, a rapport was established that made our bringing them into the group discussion more possible. We have tried to be neither unconvincing nor coercive, and above all desired to prevent an emotional deafness to mental hygiene; thereby symbolizing a faulty relationship between teacher and pupil. All of us are too reminiscent, unfortunately, of the teachers in our lives who have checked our enthusiasm in a subject solely by their personal contact with us. In that way, many an intelligence rating has been lowered by our emotions. It is the responsibility of the teacher to prevent such a happening, as his function is to develop, not inhibit potentialities.

Closely allied or coupled with the importance of teacher-student attitude is the too frequently disregarded necessity of the teacher finding out how much the student already knows about the subject to be taught and how much the student at the time is capable of grasping, both intellectually and emotionally. We found out that, as is the usual condition, these graduate nurses had had no adequate course in psychiatry during their training. Some had attended lectures and read since graduation but few had any appreciation of the meaning of psychiatry and mental disease. We therefore had to begin at rock bottom, which has the advantage of eliminating any prejudice or faulty knowledge of the subject. Having determined how little they knew about mental hygiene, the next task was

gradually to ascertain how much they then could learn.

The extension of knowledge or learning is dependent upon cerebral cortical endowment and the desire to learn. The cortical equipment of the group was more than adequate for a sound evaluation of mental hygiene. They were of normal intelligence capacity, otherwise they could not have arrived at and accomplished in the nursing field what their positions demanded. Our job was first to attract their attention and arouse their interest to such a degree that they desired and felt the need of more information about human reactions, and, secondly, to satisfy this need. May we say that in the beginning ultra-technical words were omitted based upon the fact that only through verbalization can an idea become conscious and thereby understandable. If wholly unfamiliar words had been used the extension of the field of psychiatric knowledge would have come to nought. Gradually, as the ideas were assimilated and digested, then the technical words became associated with and attached to the ideas.

The following topical outline indicates the approach we made. After we distinguished between neurology, psychiatry, mental hygiene, and psychoanalysis, they then knew in what realm the discussions were to be. Following this, we took up the basic principle of the organism-as-a-whole or the totality of the living being, whether plant or animal, and considered the life reaction, for example, of the ameba, the fish, the tiger, and man. We viewed the psyche as the manner by which each organism conducts itself in its particular life setting and dwelt upon the fact that mentality is not an organ or system that has been added to or superimposed upon other organs or systems at some era in the process of development. We therefore eliminated the unsound conception that is so prevalent, of heredity versus

environment and mind as separated from body.

Even though the final word regarding instincts has not been said, we, nevertheless, tried to show that the instinctual basis of behavior is common to all mankind and that the degree, intensity, or quantity of response determines health or ill health and that this determination has a discoverable causation traceable to the relationship of parents to each individual child, who in turn has a certain biological equipment. In taking up the psycho-sexual development of a child, the family setting was again gone into more fully. It was our hope that the term "sex" would be enlarged in their opinion and not be thought of as a curse or blessing from mother nature, in this way to view masturbation, homosexuality and perversions as stunted emotional development rather than moral degeneracy. The term "sexual satisfactions" was divorced from the limited sphere of prostitution and immorality.

To one discussion we gave the title of "The Contagion of Mental Disease" and by explaining the mechanism of identification somewhat clarified the old adage of "Like father, like son." In this way habit formation and response to stimuli were made synonymous with the dynamics or the manner by which the specific organism operates. Other mechanisms were, of course, explained and an attempt was made to illustrate how recognizable they are in types of both normal and abnormal personalities. For example, when a patient formerly might be described as uncooperative or untruthful, terms alas, which too frequently appear on the case records of every organization, an attempt was made to understand what he was trying to do and what emotional gratification he was seeking.

Because of the important rôle of the unconscious in one's mental life, the structure of the psyche and its develop-

ment were discussed in relation to reactions that are not regarded as abnormal. In this way the gap between the normal and the pathological mind was bridged and a correlation between mental hygiene and such social problems as alcoholism, unemployment, or communism, seemed pertinent. Often, the nurses would request a discussion of such problems—to illustrate a specific case. The morning after "Two-Gun" Crowley was electrocuted because of his having murdered a New York policeman, the hour was devoted to looking at the antisocial and criminal man through the lens of a psychiatric microscope. Endowed with only a limited intelligence, the son of an ignorant peasant girl and policeman, born out of wedlock, boarded at baby farms, with no family life in early years, with no one who cared for him but a foster-mother with whom he lived in later childhood, and with a fixed paranoid trend toward policemen and social authority—all of these facts made his crime more understandable to the group.

At various meetings other specific cases were analyzed in the light of causation in order that the students might appreciate that to understand the motivation of surface behavior is just as necessary for therapy as to determine whether or not a fever is caused by a typhoid or tubercle bacillus.

It may seem irrelevant to mention a problem that too often presents itself in the present-day teaching of mental hygiene and psychiatric principles. It is one which we have tried to eliminate because we believe it must be eradicated before mental hygiene can come to its just fruition. We refer to the cleavage existing between the medically and non-medically trained personnel. Several years of personal experience have brought us in touch with both groups and there has not yet been great progress made in healing the breach due

to their previous training. The medical schools and hospitals, the only places where physicians and nurses can get their training, have stressed organs, systems and body; therefore, the human being is understood only through anatomy, physiology, and pathology. On the other hand, social workers and educators are also alive to the mental hygiene movement, partly because they are meeting a need that was not met by the medically trained person, either physician or nurse. In turn, they are educated in our general colleges and schools of social work where the emphasis of man has been placed on that subtle thing called "mind" and only through academic psychology, philosophy, economics and sociology, has he been explained. Unless the two groups can come together, mental disease will not be understood and prophylactic measures in our homes and schools will be wanting. We do not propose that educators and social workers must study medicine, neither do we feel that a capable nurse must be also a doctor of philosophy, but if any of us, in whatever sphere, are to play our part in helping individuals deal with themselves in life's setting, we cannot consider human reactions as a psychological phenomenon coming from out the "blue," nor as the result of chemical imbalance, but rather regard behavior as the motor response from external and internal stimuli to the entire organism and not from thought processes alone.

This, we trust, has been our approach in teaching these nurses. We have omitted discussions regarding various schools of psychopathology, and we have not given them the symptomatology of the different clinical entities met with in psychiatry. We have adhered to no set curriculum except that determined by their desire to learn more.

Mental illness is a social problem; so

are tuberculosis and diphtheria; but all must be thought of in the words of Francis W. Peabody when he said, "What is spoken of as a clinical picture is not just a photograph of a man sick in bed, it is an impressionistic painting of the patient surrounded by his home, his work, his relations, his friends, his joys, sorrows, hopes and fears." A knowledge of mental hygiene gives to these words a real meaning.

In order to evaluate our results we asked the nurses recently to express in a few words whether or not the mental hygiene service had been of value to them in any way. They were told that the opinions could be signed or unsigned, as they wished. Twenty-six replies came in—of these, 1 wrote "No"; another response was "I attended very few of the lectures so cannot give a fair opinion. The few I attended I did not enjoy as I always feel that Dr. Adamson is too positive in her assertions and creates a definite negative reaction in me." The other 24 replies were positive that the service had been of definite value by obtaining better results in the following ways, as expressed in their words:

In practical work in the field; approach to families; solving reasons for refusals and combating refusals; understanding the human side of life; better contact and more tact; realization that our failures are in many instances due to faulty approach; adjustment to my own family problems, also staff; understanding more problems with which we are confronted in our families; effort to take away one thought from each discussion; development of greater tolerance and understanding of people; recognizing and handling situations met in the homes and school, particularly in dealing with children and teachers, so that now the pupils, teachers, and nurses have more understanding of each other; improvement in group adjustment; applying these methods to everyday work have found them very effective; being more able to account for attitudes of many contacts; helping me to see why coöperation could not be obtained due to mentality of the individual.

Based upon these opinions and those of other staff members, we can now say with conviction that a mental hygiene service is a desirable component of a health center, particularly in the educational value to the nurses.

Our project is now completing the second year and we believe a continuation of it is more than justified if we expect nurses to render a real service in the field of public health.

Unemployment

THE Save the Children International Union with headquarters at Geneva recently decided to make a study of the effects of unemployment on children and adolescents. It is expected that this study will be of practical value in showing among other things the need for more extensive child welfare work and the mistake of curtailing it for reasons of economy. The study will also allow a comparison of the effectiveness of the

measures taken in the different countries.

At first a detailed study in a number of countries was planned, but later it was decided to limit the study to Belgium, Germany, Great Britain, Hungary, Switzerland, and the United States, and to publish the report in the near future.—*Nouvelles de l'Union Internationale de Secours aux Enfants*, Geneva, Oct., 1932.

Effects of Air Contaminants on the Natural Light of Cities*

H. B. MELLER AND MARY E. WARGA

Air Pollution Investigation, Mellon Institute, Pittsburgh, Pa.

SINCE 1911, Mellon Institute of Industrial Research has been interested in the problem of air pollution, particularly in industrial communities, and has in progress a program of investigation of the causes and effects of air contaminants, especially those resulting from the combustion of fuel.

Of major importance in a study of the effects of air pollution is the determination of its action in obstructing natural ultra-violet radiation, particularly in the shorter wave lengths. The primary purpose of the present paper is to give some data obtained from 12 months' continuous records of ultra-violet radiation in the region below 3,350 Å. Seasonal and certain monthly, daily, and hourly variations are shown; reception on clear days is contrasted with that on partly cloudy days, on cloudy days, and on days when there was a blanket of light smoke. The paper should be considered one of a series, the first of which has been presented elsewhere.¹

Data are taken on the roof of the City-County Building in Pittsburgh, which is 9 stories high, with the flat roof 163 ft. above the street—933 ft. above sea-level.

The apparatus employed has been described at length in the paper cited. In consequence, the description given in the present contribution will be condensed, and sufficient only to make the findings understandable.

INSTRUMENTS

Receiver—We have been and are using a Rentschler Ultra-violet Meter designed primarily as a dosage meter to determine the amount of ultra-violet necessary to produce erythema. At the inception of the study, necessary modifications were made in insulation, housing, capacity, etc., to adapt the instrument for continuous use outdoors.

The essential feature of this meter is the photo-electric cell with Corex D bulb; the uranium plate cathode of the cell has an area of approximately 12 sq. cm. Current flows only when ultra-violet radiation between the approximate limits of 2,700 Å and 3,350 Å falls on the cell.

The amount of current is proportional to the intensity of the ultra-violet, although this current is very small—approximately 0.1 micro-ampere for fairly intense radiations. It is necessary to amplify this small current and hence, actuated by a 180-volt battery of dry cells within the cabinet, a glow relay or starting anode tube is placed in the circuit. Connected to the ultra-violet cell is a condenser, which is slowly charged by the current trickling through the cell. Thus the time of charging the condenser to a fixed quantity is proportional to the intensity of radiation. When this fixed quantity of charge is reached, the condenser spills over and the tube "breaks down" and an impulse of current flows, operating either a click recorder or a graphic recording meter.

This photo-electric cell, properly

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

used, has a constant sensitivity within the range of measurable accuracy and, according to Rentschler, shows no change or aging over a considerable period of use. Different cells, however, have different sensitivities and each must be separately calibrated against a quality of source closely similar to the one to be measured. Particular attention must be given to insulation of connecting leads, to prevent leakage to ground or around the condenser.

It may be noted that the instrument actually integrates or records intensities and amounts (or time-intensities) of ultra-violet radiation, but at present, for lack of the proper terminology, there can be no absolute units of value assigned to the data. In these studies the designation "Rentschler Ultra-violet Unit" is used (a unit being, arbitrarily, one click from the meter), in terms of which the readings are given. The responses were not uniform through the year, because neither the same box nor the same cell was used throughout, and because condenser capacities were changed from time to time to increase or decrease the amount of ultra-violet necessary to break down the glow relay tube. The meters were therefore checked as described below, and the record of responses brought to a uniform standard, which was fixed at 29 clicks per minute.

Checks are made frequently (normally once a week) against a Mazda Type S-1 lamp. This lamp is very susceptible to temperature changes and to position of burning. The method of checking used here is to burn the lamp in a vertical position for 30 minutes, then to take the response of the meter at a definite distance (24") during the next 15 minutes. If more time is needed, the lamp is allowed to cool and the process is repeated.

Solar Table—With the present construction of the Rentschler meter, the cell is fixed in a position perpendicular

to the base of the box. Therefore, in order that direct sunlight shall fall normally on the cathode, the box must be at an appropriate angle and must rotate in a plane parallel to that of the sun's apparent path. To provide for this position, the solar table was devised. It consists of a table set on a north and south axis and carrying a circular disc, set at an angle of $40^{\circ} 30'$, corresponding to the latitude of Pittsburgh. To this is attached a cradle—for the meter—with an adjustment for declination. The table is connected, through gears and shafting, to a $1/6$ H.P. synchronous motor, which has a speed of 1,800 r.p.m., the table making one revolution per day. Thus the cathode of the photo-cell is kept normal to the sun.

The meter is covered with a bakelite box, with a 5" sphere of Corex glass, frosted inside, over the cell. Similar Corex bulbs were tested by the Westinghouse Lamp Company to make certain that no appreciable solarization could occur.

While the cathode of the photo-cell is normal to the sun, it receives radiation from an appreciable angle. In addition, the frosted Corex bulb is integrating and adds to the amount of sky-shine received. Hence the total amount of ultra-violet radiation which reaches the cell is the direct plus a considerable percentage, but not all, of the diffuse or reflected radiation.

Recorder—The impulses from the meter are transmitted to a Westinghouse watt-hour demand meter, type RA; the pen is set to trip at 5-minute intervals.

Results from the records are chiefly comparative, and it should be remembered that very little solar radiation reached the cell that was of wave length shorter than 3,000A, hence not of maximum effectiveness in producing erythema. To correlate graphs with erythema, it may be helpful to note that

the maximum biologically active ultra-violet values at midday represent a minimum perceptible erythema in about 20 to 30 minutes.

EXPERIMENTAL FINDINGS

Figure I is a comparison of a clear day in June with a clear day in December. The values indicated are the recorder readings at 5-minute intervals throughout the day. Note the effect of light clouds during the middle of the day in June.

Wherever possible, checks were made to determine the accuracy of methods used. In this case, for example, the altitude of the sun at noon on the day in December was found to be practically the same as the altitude of the sun at that time on the day in June when an equivalent amount of radiation was received. This indicates accuracy of method and linearity of response of the meter.

Figure II indicates, for each month from July, 1931, to June, 1932, the average time of sunrise and sunset and

the average time of beginning and ending of ultra-violet radiation below 3,350A. Considering as maximum the highest value in ultra-violet, as received at midday on a clear day in June, the chart indicates the average beginning and ending time for 75 per cent, 50 per cent, 25 per cent, and less than 25 per cent, respectively, of this maximum. The reason for making such divisions is that only a part of the ultra-violet received is in the "therapeutic band," which is between 2,950A and 3,150A. Those desiring to estimate when this band may be expected to be present may do so from the chart, keeping in mind the limitations within each division. The spectrographic study to determine shortest wave lengths at different times during the year is not completed, and hence cannot be included in this paper.

The time given on this and other charts referred to in this paper is local apparent time.

In Table I are given averages of daily totals, averages for days when there was

* Includes 3 days of rain.

a light smoke blanket all day, and for days when there was no such blanket. The number of days used in making up these averages was 75 per cent of the total number of days in the year. Those omitted included days on which the meter was taken inside for checking, the records for such days being incomplete; days on which the meter was not

operating by reason of temporary failure of a relay (which occurred several times, owing to the variable strain on the spring of the relay caused by the great variation in angle as the box revolved with the solar table); failure of glow tube (which happened twice); loosening of cement between base and cover of photo-cell; and days when the

FIGURE II

morning record indicated the possibility of leakage caused by moisture. The averages are incomplete to this extent, but the trends are correct, and it is believed that the averages are approximately so.

The effect of smoke and of "zero" days—when no ultra-violet at all was received—will be considered later.

In segregating the clear, partly cloudy, and cloudy days, the system used by the U. S. Weather Bureau has been followed: 1.0 = completely overcast; 0.1 to 0.3 = clear; 0.4 to 0.7 = partly cloudy; 0.8 to 1.0 = cloudy. It is obvious that, while this scale gives the sky condition as to extent of cloudiness, it does not include, in the latter two groups, the extent of direct sunshine. The classification is used as mentioned, however, for this general analysis; for a more detailed study for later presentation, a combination of the percentage of cloudiness and the extent of direct sunlight will be followed. Days of light smoke are those on which the visibility was at no time greater than 8 miles, as a result of smoke and dust as distinguished from other obstructions to vision. On many other days there

was smoke during the earlier morning hours and the later afternoon hours, but such days are not included as days of light smoke in this paper.

In order to indicate the trend through the seasons, Figure III is shown for the two hours from 11 a.m. to 1 p.m. (1 hour on each side of noon), for clear periods only. The averages are in Rentschler ultra-violet units per hour. Attention is again called to the fact that the responses from different meters will not be the same; while, with another meter, trends would be comparable, for direct comparison of amounts the records would need to be adjusted to the same number of clicks per minute (29) under the same standard conditions as mentioned previously. In addition, the effect of "zero" days is indicated, the solid part of the column being the average for all days, while the height of the open portion indicates the average for the month excluding "zero" days.

The hourly averages 11 a.m. to 1 p.m., for clear days only, are again shown in Figure IV. It will be noted that, with one exception, the periods when there was a blanket of light smoke occurred during the heating season.

Figure V is an attempt to show, graphically, not only a comparison between clear periods (11 a.m. to 1 p.m.),

FIGURE III

partly cloudy periods, and cloudy periods, but also in each group the difference between days designated as

analysis, which will be made subsequently.
At the Pittsburgh station of the U. S.

having light smoke and days not so designated. This latter comparison is not so trustworthy for partly cloudy and cloudy days as it is for clear days, because of the variable intensities within these groups, owing not only to differences in extent of cloudiness, but also to the type of clouds. The chart points to the desirability of a closer

Weather Bureau is a pyrheliometer, which records the intensity of total solar radiation (infra-red, visible and some ultra-violet). Figure VI is a correlation of total solar radiation with ultra-violet below 3,350A, as recorded by the Rentschler ultra-violet meter on the roof of the City-County Building, both taken for clear hours only between

10 a.m. and 2 p.m. The ordinates on the chart are Rentschler ultra-violet units, the abscissae are from the pyrheliometer, in gram-calories per sq. cm.

DISCUSSION OF RESULTS

It should be kept in mind that the uranium photo-cells used in the Rentschler-ultra-violet meters from which the accompanying data were taken are not sensitive above 3,350 Å; the radiation reported is between that wave length and the lower limit of sunshine.

The time during which such radiation was received on clear days varied between 5:30 a.m. to 6:35 p.m. ($12\frac{3}{4}$ hours) for June, and 8:05 a.m. to 3.50 p.m. ($7\frac{3}{4}$ hours) for December.

Only a part of this radiation is in the therapeutic band, so for purpose of comparison the time chart (Figure II) was prepared to show duration of

various percentages of the maximum—maximum being the amount of radiation received at midday on a clear day in June. On this basis, and considering the time between sunrise and sunset for each month as 100 per cent of possible time, it will be noted that the total time between the first and the last response of the cell was about 80 per cent of the total number of sunshine hours throughout the year, with variations from about 75 to about 85 per cent.

Radiation equal to or greater than 25 per cent of the maximum intensity extended over an average of 45 per cent of the number of sunshine hours, with variations between 66 per cent in June and 14 per cent in December; for 50 per cent of maximum, the percentage was 24, with variations from 48 per cent in May to zero in December; and for 75 per cent of maximum, 8 per cent average varying from 25 in May to 1 in February

and zero in October, November, December and January.

The maximum radiation received in a 5-minute period on the clear day in June, shown in Figure I, was 1,000 Rentschler units, while in a 5-minute period on the clear day in December it was 430 units.

Comparisons between clear, partly cloudy and cloudy days, with and without smoke, are limited in this discussion by the broadness of the classifications used, which are standard of the U. S. Weather Bureau. Using their definitions, ratios between high and low months, for totals of daily averages of ultra-violet radiation below 3,350A, comparing June and December, for example, were: for clear days, 3.5 to 1; for partly cloudy days, 4.5 to 1; for cloudy days, 8.5 to 1; and for all days, 6.0 to 1.

The effect of a blanket of light smoke, in obstructing ultra-violet radiation, has been indicated in Figure IV. There were 70 days of light smoke (according to the classification mentioned) in the 6 months October to March, and 15 days in the 6 months April to September. During the 6 months October to March, 50 per cent of the clear days, 26 per cent of the partly cloudy days, and 62 per cent of the cloudy days, or 49 per cent of the total were days of light smoke. On the

other hand, during the remaining 6 months of the year, 9 per cent of the clear days, 6 per cent of the partly cloudy days, and 22½ per cent of the cloudy days, or 12 per cent of the total were days of light smoke.

It was mentioned that 75 per cent of the total number of days in the year was used in the tabulations and charts presented. If all days are included, 41 per cent of the period October to March, and 8 per cent of the period April to September were days of light smoke. The proportion is about 5 to 1, whether all or 75 per cent of the number of days in the year is used.

As brought out previously, this paper is really a progress report—a brief general analysis of a part of the data taken during the period. Closer analyses, to be made of these and other data on hand, will be made the subject of other papers in the series. Then, too, further studies will be made, including a comparison of the uranium cell with a titanium cell recently developed by Rentschler.²

Young Unemployed

ACCORDING to a recent ruling by the Federal Government, the maximum age for admission to the continuation courses for unemployed has been raised from 23 to 25 years. In these courses practical work is supposed to occupy about four-fifths of the time. Emphasis is placed on close coöperation among all the public and private agencies interested in unemployed young people for the purpose of obtain-

ing the necessary food and working clothes for those attending the vocational continuation courses. The ruling specified measures for unemployed who have been previously engaged in some work and for those who have just left school.

An appropriation for this work has been made by the Federal Government. —*Deutsche Ztschr. f. Wohlfahrtspflege*, Berlin, 9, 1932.

Antirachitic Activation of Milk by Direct Irradiation With Ultra-violet Rays*

G. C. SUPPLEE, PH.D., F.A.P.H.A.

Director, The Dry Milk Company Research Laboratories, Bainbridge, N. Y.

DURING the past few years practical methods have been developed for the economical production of irradiated milk. Clinical and laboratory experiences have proved the value of such milk for the prevention and cure of infantile rickets. These facts may very properly serve as a basis for discussing direct irradiation of milk from the public health as well as the technical point of view. Before discussing the irradiation of milk as a matter of commercial practice, it is desirable to examine the basic conditions upon which such a development may be predicated. An extension of the practice must, of necessity, take into account the existence and solution of practical problems, both dietary and industrial.

The prevalence of rickets among children less than 2 years of age is acknowledged.¹ Such data indicate that it is the most common nutritional disease of childhood. Its geographical distribution is almost universal, varying in intensity with seasonal and climatic conditions, and influenced by density of population. Surveys conducted during recent years indicate that from 50 to 96 per cent of the younger children in the larger cities of the United States suffer to some degree from rickets. This condition challenges the attention

of those concerned with the maintenance of the public health, not only from the standpoint of infant welfare, but also from that of conservation of adult life and national efficiency. The following statement from a British source² is pertinent:

The disease has been long prevalent in this country, and though relatively non-fatal, it is one of the most fertile of the crippling and disabling diseases of childhood. . . . Rickets is a serious factor in national inefficiency, for it often leads to structural malformation of bones and teeth, to a lower power of resistance, and to the occurrence of respiratory complications. Holt observes that the encroachment upon the lungs by a thoracic deformity may in itself be enough to keep a child in delicate condition and retard its growth; such a condition is a constant invitation to acute attacks of bronchitis and pneumonia.

Huldschinsky's³ discovery of the curative effect of the rays from the quartz mercury vapor lamp when applied to rachitic infants was soon followed by those of Hess⁴ and of Steenbock⁵ that certain foods could be endowed with antirachitic properties—that what we now know as vitamin D is synthesized in inert material by a mere exposure to suitable radiant energy. The basic character of these discoveries placed at our disposal the fundamental knowledge necessary for the creation of new agencies for the suppression and elimination of infantile rickets. This disease is with few exceptions prevented by a proper dietary

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

containing an adequate quantity of vitamin D.

The early reports emanating from American and European sources indicated the efficacy of irradiated fluid or dried milk for the prevention and cure of rickets in infants as well as in experimental animals. These stressed the favorable clinical and biological manifestations, but gave little or no constructive data in regard to the character and amount of activating energy applied to the milk during irradiation. Exposure periods varying from a few seconds to 2 hours were used. Obviously such wide differences in technic were bound to cause variable properties in the irradiated product, and to foster skepticism as to the merits and practicability of direct irradiation of milk, as holding promise of anything further than an interesting laboratory demonstration. Much was left to be done before the value of the basic discoveries could be applied in industrial practice with reasonable assurance of even mediocre success. However, these early demonstrations served a most useful purpose in calling attention to possible developments of major importance, and to the necessity of a standardized method as a prerequisite to extended adoption for use in the treatment of the general milk supply.

Since milk is the sole or major article of diet of every child during the age of greatest susceptibility to rickets, the desirability of having available a milk with a self-contained adequacy of vitamin D for the prevention or cure of rickets is at once obvious. Such a product would provide a new type of prophylaxis, simple in application, economical, and entirely free from the inherent handicaps involved in the use of the better known specifics. However, such an achievement presupposes the correlation and control of basic factors concerned in the irradiation technic. Responsibilities of no small moment are

also involved in the general distribution of such a milk; particularly when it is relied upon as the sole protective agent. Notwithstanding the lack of uniform methods and of definite knowledge regarding the control of energy applied in the early experiments, practically all the clinical results were remarkably free from evidence of secondary or toxic effects resulting from the use of irradiated milk.

The industrial application of methods for the direct irradiation of milk must take into account numerous inter-related factors. Facilities must be provided for the exposure of large volumes of milk to suitable ultra-violet radiations within short periods of time. In order that the cost of the treatment may be kept to the lowest possible minimum, the accessory equipment must be simple in construction and capable of efficient and uniform operation without the necessity of providing especially trained or skilled labor. The equipment assembly and operation which least disturbs the usual routine of milk plant activities is obviously most desirable. Since the active radiations do not penetrate milk to any appreciable depth, 0.1 mm., and since the activation of the pro-vitamin is dependent upon direct exposure to the radiant energy, all particles of the milk must come in contact with the rays.

A certain portion of the antirachitic wave lengths, as well as longer wave lengths, are reflected from the milk surface.⁶ The amount of such reflection is dependent upon the character and intensity of the radiations and angle of incidence. Suitable methods for the application of the energy and its uniform distribution must be provided in order to maintain a proper intensity of the incident radiations. This involves a determination of the distance from the source of energy to the milk film, and the use of reflectors of predetermined design and placement. These observa-

tions will serve to illustrate that the mechanics of milk irradiation from a commercial point of view involves more than an incidental and promiscuous exposure to ultra-violet rays. Such determinations are of importance in so far as they permit progress in the standardization and synchronization of the operating details necessary for the uniform production of a dependable and satisfactorily activated milk suitable for commercial distribution. The industrial irradiation of milk not only demands a simple and inexpensive method based upon specifications, but the results must meet the requirements of a critical clientele; the treated product must be acceptable to the public and its enhanced nutritive properties must be measurable in terms of benefit to the human subject and not solely in terms of laboratory assays.

A commercial method has been developed wherein these results are achieved. The method has been subjected to the crucial test of nearly 6 years' continuous operation in a commercial milk plant.^{7, 8} The basic features mentioned, as well as others of equal or greater importance, have been embodied in this unit, having a normal capacity for the treatment of slightly more than 5,000 quarts of milk per hour. The milk is exposed uniformly in the form of a moving film which receives the rays at constantly changing angles of incidence, varying from 0 to 90°. The cycle of exposure to this range of impingement angles requires approximately 0.3 seconds. The thickness of film is maintained at substantially 0.4 mm.; the time of exposure does not exceed 16 seconds. In addition to the arc lamps and electrical accessories the equipment is similar to that common in many milk plants. Carbon arcs of the flaming arc type are used. Synchronized units for which standard data have been determined may be assembled with a capacity of as low as 625 quarts

per hour; larger units may be assembled in any multiple of this minimum, and operated with equivalent efficiency.

The intensity of the radiations applied per unit of time is of paramount importance in determining the degree of antirachitic potency. A high intensity or a high rate of energy input per unit of time is necessary, not only for obtaining a satisfactory degree of potency, but also for the prevention of deleterious secondary reactions. Extended investigations^{6, 7, 8} have shown that the synthesis of the antirachitic factor in milk is practically instantaneous, providing a suitable quality and quantity of radiant energy is used in conjunction with a perfected mechanism permitting an exposure of the pro-vitamin to such energy. In contrast with this, the development of objectionable features requires a time factor of greater duration than that required for antirachitic activation. The development of adverse manifestations is due primarily, if not solely, to an extended exposure, rather than to specific wave lengths within the now known antirachitic range. The practical significance of these observations is that with suitable radiations of sufficiently high intensity the conversion of a relatively large proportion of the antirachitic pro-vitamin takes place before other secondary reactions are manifested.

Various sources of radiation are capable of yielding a suitable quality and quantity of energy for the activation of milk under the conditions described. However, those sources from which the energy emission is constant and least subject to external influences, are to be preferred. Certain carbon arc sources are particularly suited to meet commercial requirements.^{7, 8, 9} The carbon arc is of such a nature that under constant electrical conditions, namely, constant current and voltage of the arc stream between electrodes of a

Production of Antirachitic Milk by the Feeding of Dairy Cattle*

J. G. HARDENBERGH, V.M.D., AND L. T. WILSON, PH.D.

MILK has few defects as a perfect and complete food; it more nearly satisfies the requirements of complete nutrition than does any other single food product. The recognition of the defects of milk, and the character of these, constitutes an interesting chapter in the biological chemistry of recent years. It is known from chemical analysis that good milk contains excellent—if not optimum—proportions of protein, fat and carbohydrates, and of calcium and phosphorus; but it has taken the newer bio-assay methods to evaluate milk on the basis of its content of essential biologic factors such as vitamins, and certain mineral elements such as iron and copper.

A few years ago the evaluation of food products as to available nutrients was largely a matter of chemical analysis and calorimetry. It has been appreciated only within recent years that two bottles of milk—identical in composition according to the usual chemical tests—can be widely different in nutritive values. The idea and the ideal of “building” a milk of optimum biologic value is relatively new. While the use of various supplements to make up for the deficiencies which commonly occur in modern dietaries may be satis-

factory, we feel that it is well worth while to make our common foods nutritionally more complete. It has been said by a leading authority on nutrition that “the place to get vitamins is in the market, in the grocery store, from the milk man, and from the garden, and not from the drug store.” The one exception to this has been in regard to vitamin D, which occurs in most common foodstuffs in only very limited amounts.

It was recognized that the composition of cow's milk with respect to its content of proteins, fat, lactose, and some of the minerals, is largely under physiological control and not appreciably influenced by the feed of the cow, although with respect to some of the vitamins and other less known biologic factors, milk does show considerable variation, depending upon the feeds furnished the cow, and there is thus introduced seasonal fluctuations in the nutritive and biologic character of the product.

Beginning in 1925, studies on the nutritional qualities of our milk have been made continuously in the laboratories of the Department of Chemistry of Columbia University. The vitamin A, B, (B₁), C and G (B₂) values were determined at all seasons of the year. The results “indicate that a milk which is produced under excellent conditions of stall-feeding is a uniform and good source” of the vitamins mentioned.^{1, 2}

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

Fraps and Treichler³ found that "the butter fat from cows fed cottonseed meal and hulls, at the end of 15 to 16 months contained about 2 units of vitamin A to the gm. Cows fed silage, in addition to the cottonseed meal and hulls, produced butter fat containing about 2 to 12 units of vitamin A to the gm.; cows having access to a pasture in addition, produced normal butter fat containing about 33 units of vitamin A to the gm." On a comparative basis, the stall-fed cows referred to² produced butter fat containing from 33 to 50 units of vitamin A per gm.

STUDIES ON INCREASING VITAMIN D IN MILK

It was recognized that all milks as ordinarily produced are relatively poor sources of vitamin D. This is true of the various species, including man. It was decided to investigate the practicability of increasing the antirachitic potency of cows' milk by feeding vitamin D-rich supplements.

In 1924, Luce⁴ reported that the diet of the cow appeared to be the main factor in determining the antirachitic potency of her milk. Wagner⁵ in 1926, found that cows fed for 7 months with large doses of cod liver oil produced milk with no appreciable corrective properties for rickets in infants. Feeding cod liver oil is not a practical method of increasing vitamin D because of the marked depressing effect upon the fat content. In 1929, Wachtel⁶ showed that the vitamin D may be increased by feeding irradiated yeast. In 1930, Steenbock and his coworkers⁷ reported that they had been able to increase the vitamin D by feeding 50 gm. of irradiated yeast daily.

Our first experiments were started in April, 1930. Both irradiated yeast and irradiated ergosterol were fed and compared as sources of vitamin D for dairy cattle. Three groups of cows were fed different levels of irradiated yeast; 3

groups were fed irradiated ergosterol; and 1 group served as controls. The experiment extended over a period of 4 months.

At the end of this period, samples were collected from each group, and the butter fats separated and tested for their vitamin D potencies. The results have been reported by Thomas and MacLeod.⁸ It was found that the highest levels of irradiated yeast and of irradiated ergosterol both increased the vitamin D potency of the milk to 16 times that of milk from cows receiving no supplement.

The results of this preliminary work seemed so promising that it was decided to repeat some phases of it and to subject the activated milks to critical clinical tests. In December, 1930, another experiment was started in which the supplements mentioned were again used. Since the milk was to be used over a prolonged period for baby feeding incident to the clinical trials, larger groups of cows were required. The cows were selected so that the milk from each group of 8 tested as nearly 4 per cent butter fat as possible; "master" rations containing the vitamin D supplements were prepared with exactness; a special man was detailed to insure proper feeding of the groups and a group of replacement cows was maintained so that any animal in the experiment could be replaced if necessary. In all, 50 cows were included in the investigation.

The results of this experiment, which confirmed those of the first, are summarized in Table I.

It will be noted that the groups (F and Y) receiving the higher levels of irradiated ergosterol and of irradiated yeast produced milk the butter fats from which showed potencies 32 times as great as those from the control group. This gives a milk containing approximately 160 units of vitamin D per qt. of 4 per cent milk.

CLINICAL INVESTIGATIONS

The second experiment was planned so that clinical tests on the milk could be carried out. It was recognized that such tests were essential to determine the practical value of the milks so produced.

Tests were started in New York City early in January, 1931, by Hess and his associates. The milks from the 4 groups in the experiment described (Groups E, F, X and Y, Table I) were fed to 102 infants (about 25 in each group) as their only source of vitamin D. The test was essentially prophylactic, but some of the babies showed evidences of rickets at the beginning, so that it served as a curative test as well. The infants were examined, physically and by X-ray, before, during and at the end of the test, and were under close observation at all times.

Hess and his coworkers reported the results in June, 1931,⁹ and stated that "of the four test milks, all except the weaker 'yeast milk' were found, almost without exception to prevent as well as to cure rickets." It was pointed out that by the use of the specially activated milk, the specific antirachitic factor is incorporated in the diet, thus functioning automatically and relieving the physician of dependence on the mother for administering other antirachitic agents.

It was considered advisable to carry as many babies as possible through the summer and second winter. This was done in order to answer possible questions relative to the effects of milk with high vitamin D content taken during the summer months, and also to be sure that such milks would be fully effective over prolonged periods. Accordingly, about half the babies were continued on the test until April, 1932, making a total of 15 months during which they received the special milks from the groups of cows receiving the higher levels of irradiated yeast and of

irradiated ergosterol (Groups F and Y, Table I) as their only source of vitamin D.

Hess and Lewis state¹⁰ that these infants thrived, did not develop rickets in the second winter, and that the bones showed excellent calcification on roentgenologic examination.

At the same time a clinical test was undertaken in Boston by Wyman and Butler at the Infants' and Children's Hospital. A group of cows was selected and specially fed on the higher yeast level, i.e., 60,000 units daily per cow, at the Walker-Gordon farm at Charles River, Mass. The milk was used as a curative for rickets rather than as a prophylactic. Four cases of advanced active rickets were selected, carefully examined as to physical, X-ray and blood chemistry findings, and were hospitalized prior to and during the test. In all cases, the milk was pasteurized and, in one case, was boiled for 5 minutes in addition.

Wyman and Butler conclude¹¹ that the milk used "was an effective source of antirachitic substance as determined by its ability to cause healing in advanced active rickets in infants and advanced chronic rickets in children. After 5 minutes' boiling the milk still possessed antirachitic properties." Also "the substitution of this milk for the ordinary milk in the formulas of infants would introduce an effective prophylactic and curative agent against rickets requiring a minimum of coöperation on the part of the mother." Incidentally, laboratory tests have also shown that pasteurization or boiling does not reduce the antirachitic values of milk produced by the supplement-feeding method.

EFFECT OF "VITAMIN D" MILK ON THE ANTIRACHITIC POTENCY OF HUMAN BREAST MILK

The status of human milk in respect to its antirachitic potency is not clear. Although breast-fed babies are less sub-

TABLE I

| Group | Supplement Fed | Rat Units of Vitamin D Fed Per Cow Per Day | Amount of B.F. Containing 1 Rat Unit—Grams | Relative Potencies |
|---------|-----------------------|--|--|--------------------|
| Control | none | | 8.0 | 1 |
| E | Irradiated Ergosterol | 100,000 | 0.5 | 16 |
| F | Irradiated Ergosterol | 200,000 | 0.25 | 32 |
| X | Irradiated Yeast | 30,000 | 0.5 | 16 |
| Y | Irradiated Yeast | 60,000 | 0.25 | 32 |

ject to rickets than bottle-fed babies, nevertheless the milk of the nursing mother ordinarily contains little, if any, of the antirachitic factor as determined by the rat test. Breast-fed babies require less of the antirachitic factor as we usually think of it than babies fed cows' milk.

An interesting test has just been completed at the Florence Crittenden Home in Boston, in which a group of nursing mothers were fed vitamin D milk. Samples of breast milk were obtained, pooled, and bio-assayed, and compared in potency with control samples of breast milk from mothers taking no antirachitic supplement. Bunker, Harris and Eustis¹² show that an appreciable increase in antirachitic potency of human breast milk takes place when vitamin D milk is included in the diet of the mother during lactation. They point out that this is a simple and acceptable manner of augmenting the antirachitic potency of human breast milk.

We believe that vitamin D in the diet of the mother should also have a special value as a protection against the depletion of calcium and phosphorus from her body which may occur during pregnancy and lactation.

PRODUCTION OF ANTIRACHITIC FLUID MILK

The experiments briefly recounted here have involved a number of con-

siderations of great fundamental importance in practical application. These include the selection of a suitable antirachitic supplement for feeding the cows, the desirable potency to be attained in an antirachitic milk, the maintenance of uniform potency, the potency of and amount of supplement to be fed, the effects of prolonged administration of vitamin D-rich supplements on the health of dairy cattle, adequate control methods to insure reliable potency, and so on. Fortunately the experiments were so set up that the answers to many of these questions were readily obtained; special studies have been and are being made to answer others. The data brought out by Thomas and MacLeod in the experimental work with cows, by Hess and by Wyman and their associates in the clinical studies have served as the basis of methods and standards for the production of antirachitic fluid milk by the supplement-feeding method.

VITAMIN D SUPPLEMENTS FOR FEEDING DAIRY CATTLE

So far, the results indicate that irradiated dried yeast of known potency is the supplement of choice. It is easily incorporated in the grain ration by thorough mixing to insure uniform distribution. As noted by Thomas and MacLeod, some antirachitic supplements may be utilized more efficiently than others by the dairy cow (Table I). On the basis of total rat units fed, irradiated yeast proved approximately 3 times as effective as irradiated ergosterol in producing milk of a given potency. The fact is clearly indicated by the data cited, but doubtless there are various factors for which allowance must be made before final conclusions are drawn.

AMOUNT OF YEAST IN RELATION TO POTENCY OF MILK

In the clinical tests made by Hess and his associates, the results indicated that

CLINICAL INVESTIGATIONS

The second experiment was planned so that clinical tests on the milk could be carried out. It was recognized that such tests were essential to determine the practical value of the milks so produced.

Tests were started in New York City early in January, 1931, by Hess and his associates. The milks from the 4 groups in the experiment described (Groups E, F, X and Y, Table I) were fed to 102 infants (about 25 in each group) as their only source of vitamin D. They point out that this is a simple and acceptable manner of augmenting the antirachitic potency of human breast milk.

We believe that vitamin D in the diet of the mother should also have a special value as a protection against the depletion of calcium and phosphorus from her body which may occur during pregnancy and lactation.

PRODUCTION OF ANTIRACHITIC FLUID MILK

The experiments briefly recounted here have involved a number of con-

siderations of great fundamental importance in practical application. These include the selection of a suitable antirachitic supplement for feeding the cows, the desirable potency to be attained in an antirachitic milk, the maintenance of uniform potency, the potency of and amount of supplement to be fed, the effects of prolonged administration of vitamin D-rich supplements on the health of dairy cattle, adequate control methods to insure reliable potency, and so on. Fortunately the experiments were so set up that the answers to many of these questions were readily obtained; special studies have been and are being made to answer others. The data brought out by Thomas and MacLeod in the experimental work with cows, by Hess and by Wyman and their associates in the clinical studies have served as the basis of methods and standards for the production of antirachitic fluid milk by the supplement-feeding method.

VITAMIN D SUPPLEMENTS FOR FEEDING DAIRY CATTLE

So far, the results indicate that irradiated dried yeast of known potency is the supplement of choice. It is easily incorporated in the grain ration by thorough mixing to insure uniform distribution. As noted by Thomas and MacLeod, some antirachitic supplements may be utilized more efficiently than others by the dairy cow (Table I). On the basis of total rat units fed, irradiated yeast proved approximately 3 times as effective as irradiated ergosterol in producing milk of a given potency. The fact is clearly indicated by the data cited, but doubtless there are various factors for which allowance must be made before final conclusions are drawn.

AMOUNT OF YEAST IN RELATION TO POTENCY OF MILK

In the clinical tests made by Hess and his associates, the results indicated that

a desirable potency was present in those milks which on the basis of bio-assays, contained approximately 160 rat units of vitamin D per qt. This potency was effective in preventing and curing rickets in babies and children, the curative effectiveness being especially well demonstrated in the cases reported by Wyman and Butler.

Subsequently, 150 to 160 rat units of vitamin D per qt. of milk has become generally accepted and adopted as the standard of potency. To obtain this and keep it uniformly reliable requires careful supervision over a number of factors. Obviously, the first requirement is a yeast of known and standard potency. The manufacturers (Standard Brands, Inc.) have developed methods whereby a standardized product having a definite minimal antirachitic potency is available. The potency of this yeast is approximately 30-D and contains about 400 rat units per gm.

The dry powdered yeast is preferably incorporated into the grain ration, and thoroughly mixed to insure uniform distribution. This system insures more or less automatic and regular feeding of the yeast, and provides automatic adjustment of the amount fed to the requirements of the individual cow, since it is good dairy practice to feed grain in proportion to the amount of milk produced, and it is known that the yeast requirement for a given potency of the milk is proportional to the amount being produced. This has been determined by results obtained on individual cows, reported by Hess and associates¹³ and by results on milk for a number of herds reported by Frey and Light.¹⁴

In deciding how much yeast must be incorporated in the grain mixture to give a certain potency to the milk, the two main considerations are (1) the amount of grain being fed, and (2) the amount of milk being produced. Frey

and Light of the Fleischmann Laboratories¹⁵ have drawn up the following formula:

$$Q \times 160 \div X \times \frac{100}{454} \times \frac{1}{F} = \begin{array}{l} \text{per cent of yeast to} \\ \text{be included in the} \\ \text{grain concentrate} \end{array}$$

Q equals total quarts produced by all cows to be fed yeast

X equals For 45 lb. production — 9.2
For 37.5 " " 8.7
For 30 " " 8.4
For 25 " " 7.9

F equals total lb. of grain fed to all the cows to be fed yeast

This formula is based on a required potency of 160 units of vitamin D per qt.

Such a formula serves essentially as a guide and does not take into consideration all of the known or unknown factors involved. It is known that feeding 3 times daily gives better results than twice daily and, twice daily is more satisfactory than once a day. Whether or not the desired results are being fully attained can be determined only by bio-assays on the milk. Frey states¹⁵: "We are confident, as the result of a large amount of experimental work, that once the proper level has been reached—in other words, 160 Steenbock units per quart—it will not be necessary, provided the cows are kept under the same conditions, to test the milk each month. We believe that the feeding if accurately done, is sure to produce the desired potency in the milk."

Another point is the fact brought out by Russell¹⁶ that it takes about 20 days after yeast feeding has started before the milk reaches its maximum potency.

The cost of the yeast, calculated on the basis of 6/10 lb. per day for a cow producing 15 qt. of milk, at the present price amounts to about 1 cent per qt. In addition there is a fee for a license to use the yeast, and the expense of making such tests on the milk as may be required.

EFFECT OF CONCENTRATED VITAMIN D
SUPPLEMENTS ON THE HEALTH
OF COWS

It was considered important to note the effects of feeding concentrated vitamin D on the health of the cows. This has been done both with the experimental groups and with those that are used in the commercial production of antirachitic milk for general distribution; our cows are under constant observation as to general health, appetite, and production of normal milk, and they have daily veterinary supervision. The general health of the animals has at all times been excellent over a period of more than 1½ years. There has been no detrimental effect on the productiveness of the cows and the physical character and taste of the milk remain unaltered.

We have coöperated in an experiment in which excessive amounts of irradiated yeast and irradiated ergosterol have been fed to groups of cows for several months. This was undertaken to hasten and intensify any pathologic conditions that might result from prolonged administration of vitamin D supplements. The results¹³ may be summarized as follows:

In cows fed about 10 oz. daily of irradiated yeast—

... no increase in the phosphorus, calcium or ash (of the milk) was found, nor was there an increase in the inorganic phosphorus or calcium content of the serum.

When excessive, non-therapeutic, amounts of irradiated ergosterol were fed, a slight but definite rise in the calcium, phosphorus, and ash content of the milk resulted; these increases were less in the milk of cows which secreted a large volume of milk daily. There was also a rise in the concentration of calcium in the serum and, especially, of phosphorus.

Histological examinations of the various organs of the cows which received excessive amounts of irradiated ergosterol for long periods failed to show any lesions of the cellular structure or of the blood vessels. Analysis of the ash of the bones showed the percentages to be within normal limits.

RELATIVE EFFECTIVENESS OF
ANTIRACHITIC MILKS

One of the striking observations incident to the studies reviewed here, and referred to in another report on activated milk¹⁰ is the rather remarkable antirachitic effectiveness of such milks when compared, on the basis of rat unit potency, with other antirachitic agents such as cod liver oil and viosterol. On the basis of the number of rat units present, vitamin D milk as we have described it is more effective than either of the other two substances. As pointed out by Hess,⁸ the ratio is, 1:1.25:5.2. This means that 1 qt. of this milk, representing 160 units, has the efficiency in preventing rickets of 15 c.c. of standard cod liver oil (200 units) or of 10 drops of viosterol (830 units). It may be well to repeat that milk has excellent proportions of calcium and phosphorus, the very mineral essentials which are mobilized by the antirachitic factor, and other biologic factors present in milk of high quality may lend special potency to the product.

SUPERVISION

It is apparent that the supervision and control of antirachitic milks produced as described here, or by any other method, are matters for consideration by health authorities and food control officials. It is of the utmost importance that the production of such special milks be surrounded with adequate safeguards to protect the consumer and to prevent the marketing of sub-standard products which might reflect discredit upon qualified products. Some progress has already been made in this direction. The Wisconsin Alumni Research Foundation exercises legal control over the irradiation of various products, including yeast, for the feeding of animals. It requires a license to dairymen who wish to produce vitamin

D milk by feeding irradiated yeast, which stipulates conditions under which the yeast may be used and provides steps by which the potency of the milk produced may be controlled.

We recognize the necessity for periodic bio-assays to check the potency of vitamin D milk. These may be made in official laboratories, or in other recognized and competent laboratories under official sanction. In the case of certified milks, the methods and standards provide that the production of antirachitic milk shall be subject to the approval of the local authorities and the medical milk commissions. In one instance, the research division of a large city department of health has developed a laboratory where official bio-assays will be made. It is anticipated that the results of tests made in that laboratory will serve for a number of local medical milk commissions and the department of health, so that duplication of tests and unnecessary expense will be avoided. Also there are two qualified institutional laboratories, besides the University of Wisconsin, which are in a position to make routine tests for control.

The experience required for making reliable bio-assays for vitamin D, the relative scarcity of laboratories qualified for this kind of work, and the expense of a single test, are factors which make the routine control of antirachitic milks a problem for careful consideration. The problem is simplified somewhat by the fact that the potency of these milks can be controlled within reasonable limits by the method of production. The bio-assays must serve as a check on the efficiency and integrity of the producer. The

application of these methods must be considered as in the developmental stage, requiring the interest and help of all who would like to see milk made more complete in biologic values.

Relationships of Leucocytes and Streptococci to Fibrosis of the Udder*

G. J. HUCKER, PH.D.

New York State Agricultural Experiment Station, Geneva, N. Y.

THE significance of the presence of long-chained streptococci and cells in milk has long been a problem for milk control officials who are interested in detecting udder infections. The problem has received considerable attention by various investigators who have studied the flora of the so-called "normal" udder in an attempt to determine definitely the types of streptococci harbored in udders that are apparently normal to the casual observer. In many instances also the cell content of the milk has been studied in an effort to learn whether milk from udders which have been considered normal in most respects contain an appreciable number of cells. In such investigations milk has been selected which was normal in appearance and from cows which to all appearances were normal.

It has been pointed out by Udall and Johnson (1930) that cows may give milk that is regarded as normal although the udder may show signs of infection in the form of indurated tissue. This indurated or fibrotic tissue which is thought to be a result of the breaking down of the glandular structure and its replacement by white fibrous tissue, imparts hardened areas to the udder which may be detected by manual examination. It has been assumed that individuals showing this scar tissue

have at some time been infected, and that these indurated or fibrotic conditions found upon physical examination are the result of this infection. Certain investigators believe that once a quarter has been infected and these indurated areas developed, the quarter will never become entirely free of the infection. Under such conditions the infection is liable to re-occur at certain intervals. Other workers have preferred to believe that this scar tissue is only the result of an infection. Under such a condition it would be possible for an infection to run its course and the udder become entirely free from the invading organism and its effects, viz., leucocytes, the scar tissue remaining as an inert evidence of the breaking down of the secreting tissue. If this view is correct, the presence of scar tissue would have little significance as a means of detecting cows in a herd that may harbor infection and serve as foci of infection of the entire herd. Under such conditions scar tissue must be interpreted as meaning that the cow either is or has been infected.

On the other hand, if it is found that once a cow is infected the infecting organism always remains in the udder awaiting the proper condition for a subsequent attack upon the tissues, the presence of scar tissue becomes an important criterion for detecting cows with chronic mastitis. The question resolves itself into a study of the significance of the indurations. Does a

* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

fibrotic condition indicate a circumscribed lesion or rather a mass of inert white fibrous tissue which may contain no evidence of an infecting organism?

It has been pointed out by Hucker, Trudell and Jennings (1932) that all studies pertaining to udder flora and the constituents of milk should be carried out by using milk known to come from cows which have been subjected to a careful physical examination. If the results are to be considered as studies of milk from "normal" udders or udders known to be free from previous infections, these normal udders should be found to be free from fibrotic tissue.

The purpose of the present investigation has been to learn the relationship between the presence of cells and streptococci in milk and the presence of indurations or scar tissue in the udder.*

METHODS

Regular weekly quarter samples of milk from approximately 150 cows have been examined by the methods outlined by Hucker, Trudell and Jennings (1932) over a period of 10 months. The udders from which these samples have been secured have been examined at irregular intervals for the presence of white fibrous tissue, by the methods proposed by Udall and Johnson (1930). Such a routine not only gave information regarding the flora and leucocyte content of the milk but the pathological condition of the udders.

DEFINITION OF TERMS

As pointed out by Hucker, Trudell and Jennings (1932) two types of mastitis are recognized based upon external evidences, viz., clinical and sub-clinical. The clinical type, referred to by many

as active or acute, is relatively rare and involves an extreme toxic condition with occasional systemic disturbances. In sub-clinical (latent, chronic) type the individual may appear normal in most respects but the milk reacts in varying degrees to laboratory tests for mastitis and demonstrable scar tissue appears in the udder. Although the sub-clinical type may become more acute at certain intervals the condition never assumes the extreme conditions noted in clinical mastitis. In aggravated cases of sub-clinical types the milk may become broken down with little evidence of toxemia in the individual.

DATA

THE EFFICIENCY OF THE VARIOUS LABORATORY TESTS IN DETECT- ING CLINICAL MASTITIS

Clinical Mastitis—The condition of the individual suffering from acute mastitis is so obvious that no tests are required for its detection. If milk can be obtained from the affected quarter it is (Figure I) always broken down with

either a watery or serous appearance. The reaction is pH 6.9 to 7.4 and the catalase content is high while the amount of chlorides is always above normal.

It is only with difficulty that organisms can be isolated from the secretion of the infected quarter. Direct

* It is realized that voluminous literature exists dealing with the relationship of leucocytes and streptococci in the udder and their significance in udder infections. A complete bibliographic review is being prepared and will subsequently appear. For a complete published discussion of this subject reference should be made to Breed (1914).

FIGURE II—EFFICIENCY OF VARIOUS TESTS UPON MILK TO DETECT MASTITIS

microscopic examination, even of samples previously incubated, rarely reveals long chained streptococci, while cultural methods add little more possibility of isolating organisms.

THE EFFICIENCY OF CERTAIN LABORATORY TESTS IN DETECTING SUB-CLINICAL MASTITIS

The relation of fibrous tissue in the udder to the presence of cells in the milk—The significance of cells in milk has received considerable attention. Breed, after a detailed study of a series of cows, concluded that there were several unknown factors that may influence the number of cells in milk and that care should be taken in interpreting the significance on their presence in milk.

In the present investigation (Table

II, Figure III) it has been found that over a period of 10 months no quarter that was free of indurations or fibrotic tissue discharged at any one time more than 150,000 cells per c.c. On the other hand, even this number were found in only one isolated instance. Ninety-nine per cent of the normal quarters, i.e., quarters free from scar tissue, showed less than 60,000 cells per c.c., while a great majority, viz., 87 per cent, never gave a higher count than 30,000 cells per c.c.

On the other hand, 63 per cent of the quarters showing fibrotic tissue gave milk showing more than 150,000 cells per c.c. It is also interesting to note that 73 per cent of the quarters with a marked fibrosis showed over 500,000 cells per c.c. in the milk.

Hucker, Trudell and Jennings (1932) have pointed out that all quarters showing a cell count greater than 3,000,000 per c.c. give definite evidence of infection. From the results of the present investigation it is safe to conclude that all quarters showing cell counts of more than 150,000 per c.c. should be considered as suspicious, if not definitely proved to be infected with streptococci.

It was also found that not all quarters

Total tests = 5,080.

FIGURE III—MINIMUM NUMBER OF CELLS PER CUBIC CENTIMETER IN MILK FROM 124 "HIGH CELL COUNT" QUARTERS

which show white fibrous tissue discharged an appreciable number of cells. About 25 per cent of the quarters classified as showing distinct or marked fibrosis failed in any instance out of a series of examinations extending over 10 months to show cells in a greater number than 30,000 per c.c. It seems evident that there are two distinct groups of fibrotic quarters, one which never throws off cells and one which constantly, over a long period, will give milk in which the cell count is relatively high. At present it is safe to conclude that cell counts in excess of 150,000 per c.c. are always from quarters which show some degree of fibrosis. However, not all indurated quarters give excessive cell counts.

It has been further observed (Figure III) that once a quarter begins to throw off a large number of cells in the milk the numbers of leucocytes remains relatively large for months or even longer. Over a period of 10 months of observations on so-called "high count"

quarters the minimum number of leucocytes never dropped below 1,000,000 per c.c. In other words, once a large number of leucocytes appear in the milk from any quarter, they rarely diminish.

The same observations were true regarding the milk containing a small number of leucocytes. The maximum (Figure IV) number found in the milk from quarters evidencing no scar tissue when studied over a period of 10 months, never exceeded 200,000 per c.c. The individuals remained over the entire test period as "low cell count" cows.

A certain amount of variation (Figure V) between the leucocyte content of the milk from the 4 quarters of the same individual was noted. One of the most interesting observations in this connection was the fact that a greater variation could be found in the milk from quarters showing an excessive number of leucocytes than milk containing a minimum number.

RELATION OF FIBROTIC TISSUE TO THE
BROM THYMOL BLUE TEST

For some time the brom thymol blue test has been used in detecting cows that are infected and that should be classed as having mastitis. Its widespread use has raised many questions of interpretation of the results secured.

In ordinary use the results secured by this test have been classed in three groups, viz., light green, which includes

the cows giving normal milk, blue green or the suspicious cows, and dark green which always signifies abnormal conditions. Certain workers have endeavored to make finer distinctions and interpret the results as H-ion readings. The latter although applicable in the laboratory is not recommended for practical barn use.

The results of the present investigations (Table II) with the brom thymol

blue test are very similar to those secured from a study of the cells and streptococci present. In no instance during the 10-month study did a quarter free of indurated tissue give a positive reaction to brom thymol blue, though not all of the indurated quarters gave positive reactions. It is concluded that a positive reaction by this test always signifies indurated tissue in the udder while fibrosis free quarters never show it.

RELATION OF FIBROTIC TISSUE IN THE UDDER TO THE PRESENCE OF STREPTOCOCCI IN MILK

A study of 264 quarters which extended over 10 months showed that only approximately 11 per cent were free from indurations or fibrotic tissue. The remaining 90 per cent showed affected tissue to some extent. The most interesting observation (Table III) in this connection is the fact that no streptococci were found during this

TABLE III
RELATION OF FIBROSIS IN THE UDDER TO THE PRESENCE OF STREPTOCOCCI IN THE MILK

| Amount of fibrosis | Number of quarters studied | Per cent showing streptococci |
|--------------------|----------------------------|-------------------------------|
| Absent | 30 | 0 |
| Slight | 76 | 5 |
| Distinct | 100 | 24 |
| Marked | 58 | 10 |

period in the milk from the quarters that were free of fibrotic tissue. The 30 quarters which by physical examination were found to remain pliable with no hardened areas or indurations were found to remain free of streptococci. From these results it appears probable that where previous investigators found streptococci in the freshly drawn milk an examination of the udder would have shown the presence of fibrotic tissue.

These observations raise the question of the nature of the so-called "normal" flora of the udder. Some workers have assumed that a certain number of streptococci are normal inhabitants of the udder. The above data, however, indicate that such is not the case if normal udders are those that are free from fibrotic tissue. On the other hand, the conclusion should not be drawn that all udders that show indurated tissues will throw off streptococci.

Of the 234 quarters that showed in-

ductions on physical examination, only 39 per cent were found to discharge demonstrable streptococci in the milk. It is also of interest to note that, of the quarters which discharged streptococci, the milk from the majority contained streptococci in all samples, indicating that once streptococci are thrown off, the presence of these organisms is more or less constant. The indurated quarters in which no streptococci were found remained as free from these organisms over the period in which the observations were made as the quarters in which no fibrotic tissue was found. It is concluded that streptococci are found only in milk from udders that have developed fibrotic tissue. Not all indurated udders, on the other hand, eliminate streptococci.

The weekly variation in the number of streptococci in the milk from the four quarters of one individual was found to be excessive. It was noted that at certain intervals the milk from

a given quarter (Figure VI) was practically free of long chain streptococci while subsequent examinations showed relatively large numbers of them.

RELATION OF STREPTOCOCCI IN MILK TO THE NUMBER OF LEUCOCYTES

A study over 10 months of a composite sample of all four quarters of 133 cows (Table IV) has shown that 78 dis-

somewhat different results than are found in the case of the composite sample. A study of 117 quarters which (Table V) showed a pronounced fibrosis revealed that 20 threw off more than 500,000 cells per c.c. and streptococci were not observed in the milk of any of these quarters.

Observations revealed that cows with one quarter discharging an excessive

TABLE IV
RELATION OF STREPTOCOCCI TO THE NUMBER OF LEUCOCYTES IN MILK

| Number of cows | More than 500,000 cells per c.c. | | Less than 500,000 cells per c.c. | |
|----------------|----------------------------------|---------------------|----------------------------------|---------------------|
| | Streptococci present | Streptococci absent | Streptococci present | Streptococci absent |
| 133 | 78 | 0 | 4 | 51 |

charged consistently more than 500,000 cells per c.c. in their milk. A further study of these cows also showed that all contained streptococci at some period during this interval. On the other hand, of the 55 cows showing less than 500,000 leucocytes per c.c. only 4 showed streptococci at any time during these observations. In other words, if kept under observation the milk of cows eliminating large numbers of leucocytes will generally contain long chain streptococci at some period during lactation.

A study of the relationship of the simultaneous presence of cells and streptococci in quarter samples reveals

number of leucocytes will show streptococci in one of the four quarters some time during lactation. However, these streptococci are not always in the quarter showing the large number of cells. On the other hand, not all high cell producing quarters will throw off streptococci.

This peculiar relationship needs investigation to determine whether it is a fact or merely a coincidence.

A further interesting (Table V) observation is the fact that over a period of 10 months' observation 27 of these 117 quarters with pronounced fibrosis have shown neither cells nor streptococci in the milk.

TABLE V
RELATION OF STREPTOCOCCI TO THE NUMBER OF LEUCOCYTES IN MILK FROM QUARTERS WITH MARKED FIBROSIS

| Number of quarters | More than 500,000 cells per c.c. | | Less than 500,000 cells per c.c. | |
|--------------------|----------------------------------|---------------------|----------------------------------|---------------------|
| | Streptococci present | Streptococci absent | Streptococci present | Streptococci absent |
| 117 | 47 | 20 | 6 | 27 |

CONCLUSIONS

1. Milk containing more than 500,000 cells per c.c. always indicates an abnormal or pathological condition in the udder.
2. Milk containing large numbers of cells will generally continue to contain excessive numbers while milk with a small number of cells rarely shows more than 200,000 per c.c.
3. Variation in number of cells per c.c. is greater in milk containing large numbers of cells than milk showing a smaller number.
4. Alkaline reaction to brom thymol blue is never obtained on freshly drawn milk from a fibrosis free quarter.
5. When streptococci are found in aseptically drawn milk, the quarter is always indurated.
6. All quarters free from scar or indurated tissues never show demonstrable streptococci or cells in excess of 150,000 per c.c. in the milk.
7. Not all indurated quarters show streptococci or a significant number of cells.
8. Milk from a normal quarter or free of fibrosis does not contain long chained streptococci or cells in excess of 150,000 per c.c.

Meals for School Children—Yugoslavia

THE central committee of the Junior Red Cross of Yugoslavia has been active in establishing lunch rooms for school children, particularly in the villages where children live at long distances from school and do not receive sufficient food for lunch. Part of the necessary funds is provided by central and local committees of the Junior Red Cross on the condition that its members actively participate in the work of the

lunch rooms and that they cultivate their own vegetable gardens, the products of which are used for the lunch rooms. Subsidies are also granted by the local government and by private relief agencies. A recent law on primary schools orders the establishment of lunch rooms in all village schools.—*Nouvelles de l'Union Internationale de Secours aux Enfants*, Geneva, Sept., 1932.

YOUR ASSOCIATION

EVER since the organization meeting held at the New York Hotel on Friday evening, April 18, 1872, the American Public Health Association has played a leading part in molding the health organizations of our continent. The Annual Meetings have served for the contribution of reports and papers upon important sanitary questions, most of which are later published in the columns of this JOURNAL. This abundant harvest, rich in the researches and studies of our numerous committees and individual members, has furnished food to many a hungry sanitarian seeking the views of those of wider experience.

Health departments throughout the land are reporting new low death rates for 1932. Many are puzzled at these new low figures. Few of us stop to appreciate what an important contribution our Association is making by creating safeguards of human life which make possible these new health records. Undoubtedly many reasons will be given for the continued salubrious health conditions of 1932. Foremost among these causes stands forth the fact that we are still reaping the benefit of the health promotion activities which have been built up during the past two decades. Public health reflects collectively the health consciousness of the individual citizen. A community with a low diphtheria death rate is one in which the average mother has learned that every child beyond the age of 6 months should receive diphtheria protection. The absence of smallpox results from generous vaccination and revaccination. A low tuberculosis death rate means that the public has learned that this is a communicable disease and that tuberculosis comes from tuberculosis. Case-finding machinery, periodic health examinations, clinics, open air schools, hospitals and sanatoria have made their contribution, but health education is the foundation stone on which have been created community health facilities. The apparent increase in malnutrition reported from many sources offers a challenge to the health officer to fight strenuously for the maintenance of his organization. The progress of the past

and the hope for the future is in no small manner dependent upon our success in coherently maintaining our support and interest in the American Public Health Association.

Naturally, there are other factors which have contributed to the maintenance of good health. Nature has blessed us with relative freedom from such epidemic diseases as influenza, concerning the control of which we know so little. Progress in science and the development of new administrative and control procedures have been encouraged and furthered by the members and committees of this Association. There has never been a time in its history when the American Public Health Association was more deserving of the support of its membership. In spite of adverse circumstances the number of active members in 1932 showed little reduction over previous years. There is great need for concerted effort on the part of all of us to stimulate and maintain the whole-hearted support and interest of the health workers throughout the country. Do your share to stimulate this interest. Pay your own dues promptly and see that your neighbor does likewise. Constitute yourself a committee of one to secure a new member. The American Public Health Association means much to its individual members but to the children of our country and the future health of our nation it means even more.

THE DEPRESSION AND HEALTH

IN our October issue we gave our readers the Presidential address delivered at our meeting in Washington. It was optimistic from practically every standpoint. Reports from 82 of our large cities as well as from the country in general showed a decline in both morbidity and mortality, which was practically continuous. Industrial life insurance companies also report low mortality rates among their policy holders. Even tuberculosis and pneumonia showed a marked decrease over the previous year. There was a marked absence of epidemic diseases. Since that time, influenza has become epidemic throughout a large part of the United States, but the type is mild, with a few complications and very little pneumonia, so that the influence on the death rate has not been marked.

All health workers have, however, been fearful of the consequences of malnutrition in children, and our President, in spite of his optimistic outlook, warned us that if present conditions should continue, there was a practical certainty that bad results would soon be in evidence, owing to lack of food of proper quality and quantity. With few exceptions, reports have continued to be good. Certainly all of us have been agreeably surprised by the good conditions which have persisted, but it is to be hoped that no one has lulled into a false sense of security. With something like 12 million people unemployed in our country, and 40 million or more feeling the pinch due to this, it is beyond belief that favorable conditions can continue, even if we are blessed with the good weather and mild winters which have characterized the past few years. Indeed, already there are some who state unequivocally that the effects of malnutrition are becoming evident. The recent hearings in Washington were heart-rending, particularly the statements made by responsible people in regard to the miners in the coal regions. In cities throughout the United States, the budgets for relief are falling far below the estimates and the needs. From the highest authorities, such as the Red Cross, we learn that in certain sections at least, relief is only 20 per cent of what it should be. In spite of the wheat and cotton distributed through the Red Cross,

many people are still in desperate want, and conditions are getting worse as supplies become exhausted.

The Health Organization of the League of Nations has made what is practically a world-wide study of the situation. The figures in question are necessarily old, but as we have already said, conditions are almost everywhere becoming worse rather than better. The estimate at the end of 1931 was that there were between 20 and 25 million unemployed in the world, and that between 50 and 60 million were directly or indirectly affected. The United States headed the list of unemployed, with Germany second.

This review accounts for the low death rate in children by the well known fact that in periods of economic depression, marriages and births fall, but recognizes that the decline was not sufficient to account for the lowered general mortality, or the lowered infant mortality. Even among growing children from 1 to 15, who are naturally affected by food restrictions, the death rate continued to fall.

One naturally turns to tuberculosis in a study of this sort, since it is well known that food restrictions lessen resistance and favor infection. During the World War we had a striking demonstration of this fact, since the increase in tuberculosis was greatest where food restrictions were most severe, yet here again, we get a favorable report. In certain towns the decrease reached record figures, and this is true for the United States in general. Certainly the unfavorable effects of our depression have not yet become marked, judging from available records, but these are not up to date, and later returns may alter the picture.

The physical effects are not the only damage caused by the depression. There is a profound psychological disturbance among the unemployed, and this seems to be particularly severe on adolescents. In this country we have an army of boys, estimated at 200,000 by no less authority than General Glassford, who are tramping the country. These boys have been crowded out owing to the fact that many homes are now housing 2 to 3 families. They are of the adventurous and spirited type, indeed the best of their class, and unless something can be done for their relief and organization, there is reason to fear permanent injury to their characters. In some countries, clubs for the young unemployed have been created. Practically all countries studied recognize the gravity of the situation, and are intent on devising ways and means for providing for these youths useful work, which will not only furnish food and good surroundings, but will relieve the mental stress which forms so grave a feature. In this country, the matter is being considered by our federal authorities as well as by the individual states, but no comprehensive solution has yet been found.

Everyone concerned has wondered why the depression has not brought physical and mental conditions worse than we find them. The answer is not entirely easy. Doubtless our health organizations, city, state, federal, and private, have sowed good seed in the past, and we are now reaping some of the rewards of their good work and organization. A succession of mild winters and the absence of severe epidemics have also helped, but when all is said and done—the answer is not to be found in any single feature yet mentioned.

LETTER FROM GREAT BRITAIN

VIEWS ON ECONOMY REPORTS

IN the family circle the member who preaches economy is usually the least popular. Nationally also the position would appear to be the same; judging at least from some of the opinions expressed with regard to the reports of the two chief bodies who undertook to inquire into the position here and show the way to savings.

The first body to take the matter up consisted of a number of members of Parliament and was more or less self-constituted. When its report appeared, pandemonium broke loose and bore away with it, into oblivion apparently, not only the report but the chairman also.

The second body, speaking generally, seems to have fared rather better. Largely this is because it was a special committee set up at the instance of the Chancellor of the Exchequer to investigate local expenditure, and its report was official and presented by command to Parliament. In spite of this, it has not been too well received by local authorities in general, or by organizations or associations connected with or concerned in local government. In especial, very strong objection has been raised to suggestions that appear to involve interference with public health activities, not only by health officers but by members of municipalities and social organizations.

The report itself, for the reason that in some respects it does not appear to be too well informed, offers opportunities for criticism, and these it may be taken have not been neglected. One of the strongest protests against it has come from the British Institute of Social Service, a voluntary body of importance and standing. The protest is in the form of a manifesto, the signatories in-

cluding well known industrialists, educationalists, authors, publicists, and economists, among them Sir William Morris, of motor car fame, Sir Josiah Stamp, Sir Thomas Horder, the physician, recently created a peer by the King, Sir Oliver Lodge, Mr. John Buchan and Mr. H. G. Wells. The main appeal made is against any serious retrogression from the standards so laboriously erected by the local government system of the country.

Attention further is drawn specifically to the danger inherent in any attack upon the character of the local government service. In connection with this there is a fine tribute to those who work in an official capacity which it is hoped may be understood and appreciated by the public which "too little realizes the debt it owes to the great army of anonymous officials, so loyal, so devoted, so expert, so incorruptible, upon whose work the maintenance in being of the great society very largely depends."

DISAPPEARING SALARY CUTS

EVEN if there were indications of improvement this would be a difficult time of the year at which to recognize them. Nevertheless, in relation to the public health and local government service generally there have been certain happenings that may be regarded as suggesting that among members of local authorities in parts of the country the outlook appears brighter.

Included among these occurrences are the more or less complete cessation of talk about salary cuts, with hints as to the removal or modification of cuts already made. In some cases, indeed, cuts actually have been removed wholly or in part, and though the instances in

fact are few, very great value is attached to them because of the fact that they create a precedent and give others something upon which to base an appeal. That they will be so used increasingly as time goes on may be taken, and though nothing resembling a stampede is likely to occur, there will be a tendency on the part of a number of authorities to follow the example set by what may be regarded as more kindly and progressive councils.

The last time I made reference to the matter of salary cuts, I imagine I stated that largely it was a case of fifty-fifty, half the local authorities having imposed a cut graduated up to an average maximum of 10 per cent. Since then the figures have varied very little, the recent happenings referred to above giving rise to the hope that an end has been made of cutting and that the percentage of cut-free areas will steadily increase.

HOSPITAL ACCOMMODATION IN LONDON

FROM the medical point of view, one of the great changes made by the Local Government Act of 1929, which so very profoundly affected administration in this country, was in relation to hospital accommodation. Institutions which, up to the time the law altered, were part of the poor law provision, passed into the hands of the bodies responsible for local government generally, including public health. This change already even, it would seem, has led to improvements in this regard, and has been greatly to the advantage of the people. In London the effects of the alteration have been particularly marked, and though it has involved a vast amount of reorganization and labor, has caused comparatively little disturbance.

Reporting recently to the London County Council, Sir Frederick Menzies, the Medical Officer of Health, gave a very full and complete description of

the processes involved in the change over and of the position so far as municipal hospitals are concerned.

The hospital branch of the hospitals and general medical services of the county council is divided into two main sections, one dealing with general and the other with special hospitals. The work of the first-named embraces the management of some 44 hospitals and institutions, containing round about 28,000 beds. The special hospitals division deals with the management of 31 hospitals; of which 17 are for infectious diseases. The beds number about 13,500. In addition to these institutions there are, of course, the voluntary hospitals—general and special—which do not concern the county council, but which greatly increase the number of beds available for the treatment of the sick of the metropolis.

Among the general hospitals there are such institutions as St. Bartholomew's, the Middlesex, Guy's, and so on, all of them very old, established, and historically interesting. Each of them is a medical school within the University of London, the staffs being concerned in teaching and preparing the students for qualifications granted by the University of London and other universities and recognized examining bodies.

So far as teaching is concerned, it is interesting to learn from Sir Frederick Menzies's report that provision is to be made for making use of the very valuable material in the hospitals for which the county council is responsible in a manner and to an extent never attempted while the institutions were in the charge of the poor law authorities. Included in the medical staffs of the hospitals are numbers of specialists of various kinds who give part-time service as consultants or otherwise. Recently these individuals have received notice of intention to determine their appointment, a move which is regarded as more or less of a formality though it may

indicate that reorganization is intended. That it may have some connection with the extension of the use of the institutions for purposes of instruction of medical students and the placing of members of the staffs of the teaching hospitals upon those of the municipal hospitals is just possible. Even if such a change were made it would make little difference in the quality of the work done in these institutions, which, as the report of Sir Frederick Menzies shows, has attained a very high level.

HONORARY FELLOWS OF THE ROYAL SANITARY INSTITUTE

THE Honorary Fellows of the Royal Sanitary Institute of Great Britain elected in December, 1932, I note, numbered two, both being citizens of the United States of America. That one should be Professor Mazÿck P. Ravenel is a matter that affords great gratification, not only to me personally but to members of the public health service in this country generally, partly on account of his contributions to *Public Health*, the official organ of our

Society of Medical Officers of Health.

The Royal Sanitary Institute is a distinct body from the last-named Society, and in its composition resembles somewhat the American Public Health Association. In addition to including individuals officially engaged in the various branches of public health and preventive medical work as medical officers and engineers, etc., the Institute is prepared to admit as fellows, members, or associates, others who hold qualifications or are engaged in public or professional work of a recognized and appropriate type.

So far as medical officers of health are concerned, the Institute as a body is held in very high esteem, and in its fellowship are to be found the majority of the more active members in the field of public health.

The other occupant of the list of honorary fellows elected on this occasion is Dr. George A. Soper, of New York City, whose election has been a source of gratification to his engineering colleagues on this side.

London CHARLES PORTER, M.D.

New York City Bulletin

WE regret to note that with the issue of December 31, 1932, the *Weekly Bulletin* of the City of New York Department of Health ceased publication as such. In future, the Bulletin will be issued quarterly, but every effort will be made by the editor to keep up the continuity of the statistical data which have been presented in the past.

The *Weekly Bulletin* has existed in its present form since 1913, though, beginning in 1890, it was the outgrowth of a weekly summary of vital statistics published for the health officers and

registrars of vital statistics. The discontinuance at this time is due to the rulings of the federal postal authorities. The expense has been a burden to the department which was felt to be unjust and unwise. If this law can be changed and second class mailing privileges granted, it is hoped that the *Bulletin* may resume publication weekly.

All who have received this *Bulletin* heretofore will miss it from their desks. It was always well edited, good reading, and full of useful information. We hope that it will soon be revived.

ASSOCIATION NEWS

RURAL HEALTH APPRAISALS

The Second Edition of the *Appraisal Form for Rural Health Work* published in January, 1932, is being unusually well accepted and is widely used. A number of state health departments are applying it to all their county health departments.

Those interested in the appraisal of rural health work will be gratified to know that Dr. E. L. Bishop's sub-Committee on Rural Health Work has taken cognizance of the fact that special health problems exist more frequently in rural than in urban areas, through the appointment of a special sub-committee to consider appraisals of

activities designed to meet such special rural problems. This sub-committee, composed of Sophie C. Nelson, R.N. *Chairman*, Dr. Allen W. Freeman, and Dr. W. S. Leathers, is studying the problem and considering the possibility of preparing a supplement to the Rural Appraisal Form which would include definitions of the more important special problems (as a means of determining whether or not such items should be included in the appraisal of any given area) and the scoring of programs designed to meet such problems. It seems probable that malaria, hookworm, and trachoma will be the first three special problems to be considered.

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

Paul H. Brown, M.D., 265 Main St., East Haven, Conn., Health Officer
Dr. Emily F. B. Chatfield, Voluntown, Conn., Health Officer
Edward J. Howland, M.D., 25 S. Main St., Colchester, Conn., Health Officer
William W. McFarland, M.D., 620 City-County Bldg., Pittsburgh, Pa., Director, Department of Public Health
Abbott B. Mitchell, M.D., Court House, Allegan, Mich., Director, County Health Unit
John H. Mountain, M.D., D.D.S., 172 Washington St., Middletown, Conn., Health Officer
H. R. H. Nicholas, 33 Ivy Lane, Englewood, N. J., Health Officer
Paul M. Spurney, M.D., City Hall, Shaker Heights, O., Health Commissioner
Dr. Cecil J. Vaughn, Lexington, Miss., County Health Officer

Vital Statistics Section

Harry W. Gehm, M.S., 531 Walnut St., Elizabeth, N. J., Statistician

Laboratory Section

George J. Hucker, Ph.D., New York State Agr. Exp. Station, Geneva, N. Y., Chief, Bacteriological Research
Israel Weinstein, M.D., Ph.D., Sc.D., 1165 Park Ave., New York, N. Y., Teacher of Bacteriology and Hygiene
Doris E. Wilson, B.S., 403 Second St., Jackson, Mich., City Bacteriologist

Public Health Engineering Section

Lyman B. Chamberlain, A.B., Barry County Health Dept., Hastings, Mich., Sanitary Officer
Bernhard P. Domogalla, Ph.D., 803 State St., Madison, Wis., City Biological Chemist
Bernard J. McMorrow, B.S., 113 Chandler St., Boston, Mass. (Assoc.)
John A. Scarlett, Allegan, Mich., Sanitary Inspector
Wilmer H. Schulze, Ph.D., 503 Rock Glen Rd., Baltimore, Md., Chief, Division of Chemical Technology, Department of Health

Food and Nutrition Section

Christine Hall, R.N., 69 Paradise Rd., Northampton, Mass., Supt., Smith College Infirmary
Gilbert H. Hood, Jr., 500 Rutherford Ave., Charlestown, Mass., Secretary, H. P. Hood & Sons, Dairy Experts

Child Hygiene Section

Dorothy L. Campbell, R.N., 112 Brighton St., Plainwell, Mich., Health Teacher
Gertrude B. Hansen, Box 133, Houghton, Mich., County Nurse, Children's Fund of Michigan
Leone V. Hartlein, R.N., Hastings, Mich., Health Teacher
Helen Linn, R.N., 428 S. Broadway, Hastings, Mich., Health Teacher
Margaret M. Nicholson, M.D., 1801 Eye St. N.W., Washington, D. C., Child Hygienist
Mildred L. Tuttle, R.N., 119 W. Green St., Hastings, Mich., Instructor, Health Education
Marion Wetzel, R.N., Kellogg Club House, Augusta, Mich., Health Teacher

Public Health Education Section

Maria W. Bates, B.S., 410 Stuart St., Boston, Mass., Student (Assoc.)
May E. Chinn, M.D., 44 Edgecombe Ave., New York, N. Y., Student (Assoc.)
Frank K. Fairchild, 86 Lefferts Pl., Brooklyn, N. Y. (Assoc.)

G. Hamilton Francis, M.D., 1024 E. Liberty St., Norfolk, Va., Promotion of Public Health, National Medical Association
Jethra Hancock, M.D., 532 W. Main St., Louisville, Ky., Director, Bur. of Venereal Disease, State Board of Health
Mrs. Joseph Sanders, 2612 Tilden St., Washington, D. C., Chairman, District of Columbia Health Congress of Parents and Teachers

Public Health Nursing Section

Jean MacD. Clark, R.N., 246 Monroe St., Allegan, Mich., County Nurse, Allegan County Health Unit
Sister M. Laurentine Harrington, R.N., St. Francis Hospital, Pittsburgh, Pa., Principal, School of Nursing
Ann Morton, R.N., Weyburn, Sask., Canada, School Nurse
Susan Smith Nobles, R.N., 422 W. Green St., Hastings, Mich., County Nurse
Lena M. Schermann, R.N., 636 Marshall St., Allegan, Mich., Allegan County Nurse
Rena D. Wing, R.N., Health Unit, Hastings, Mich., County Nurse

Industrial Hygiene Section

Lewis A. DeBlois, 15 West 11 St., New York, N. Y., Consulting Engineer on Occupational Disease Prevention

DR. BOLT RECEIVES OBERLAENDER AWARD

RICHARD A. BOLT, M.D., F.A.P.H.A.

Dr. Richard A. Bolt, M.D., F.A.P.H.A., Director of the Cleveland Child Hygiene Association and Editor of the Child Hygiene Notes Section in the *Journal*, has been granted the Oberlaender Trust Award "to carry on a detailed study of Maternal and Child Welfare Conditions in Germany and Austria."

"The Oberlaender Trust was founded under the auspices of the Carl Schurz Memorial Foundation, Inc., by Gustav Oberlaender, Reading, Pa., as an expression of his desire to be of greater service to the American people. The trust is for the specific purpose of furthering a better understanding of the German-speaking peoples by the American people and *vice versa*." Dr. Bolt will leave Cleveland early in April.

PUBLIC HEALTH ADMINISTRATION

India—In 1921 public health work in India was transferred with certain reservations from the Central Government of India to the governments of the various provinces. A ministry of health was not provided for in this change and no such central organization exists. The activities of the Central Government are maintained by the Department of Education, Health and Lands. In transferring these health activities to the provinces certain functions were reserved for the Central Government. These include international health affairs, epidemiology, census and statistics, emigration and immigration, pilgrim traffic, major port quarantine work, and medical research. In 1929 the birth rate in British India was 34.8 per 1,000; the death rate was 24.9, and the infant mortality rate was 178.4 per 1,000 births. The death rate of 25.9 may be compared with that of England and Wales of 13.4; for the United States, 11.9; for Austria, 9.6; and New Zealand, 8.8.

Kala-azar has been prevalent in the Eastern provinces of India. It was imported into Assam in 1882 and has slowly spread. At first the mortality rate was high, 90 per cent of the cases dying, but treatment with antimony has resulted in a 90 per cent recovery rate. Cholera in 1929 was the cause of 295,434 deaths in British India. The rôle of pilgrimages in the spread of this disease is well known and attempts at mass inoculation on a voluntary basis are being made in connection with these fairs.

There were 72,482 deaths from plague in British India in 1929, a mortality less than that for 1928 but more than in 1927. Reviewing the mortality for a number of years there is evidence that

plague is progressively decreasing. One theory advanced is that there has been evolved a race of rats immune to plague. An inquiry is being made into the immunity of wild rats in different parts of India. Other causes ascribed to the gradual disappearance of plague are: (a) the exercise of a natural and common law which, as in other zymotic diseases, determine the rise and fall of epidemic conditions; (b) protection by inoculation, by sanitary measures such as deratization, rat proofing, etc.; (c) some influences acting in the flea factor.

There were 72,884 deaths from smallpox, the mortality among children under 10 years of age being 58 per cent of the total smallpox mortality. There were performed 9,579,806 primary vaccinations and 6,339,632 revaccinations. India still retains the unenviable reputation of being the greatest center of smallpox in the world.

This report from the hand of Major-General J. D. Graham, Public Health Commissioner for the Government of India, is replete with valuable tables, charts, and diagrams. There are nearly 500 pages of detailed information pertaining to the health of the Central Government and to the various provinces of India.—*Annual Report of the Public Health Commissioner with the Government of India for 1929.*

Attleboro, Mass.—In the 1931 health department report for this city of 21,982, attention is directed to popular health education.

A properly organized health department finds its duties more and more concerned with much needed education in public health. As the laws of health and hygiene are better understood, the control of disease becomes a simpler and more effective procedure. When

health education is extended to arouse an increasing interest in health, a public demand will be created for better health standards.

The program included the publication and distribution of literature and reports, as well as newspaper publicity through articles and paid advertisements. A thorough house-to-house canvass of the whole city was conducted as a part of the diphtheria prevention program. Incidentally, there were 8 cases of diphtheria, with no deaths, only 1 death from this disease having occurred in 4 years. Several extra nurses were employed to give first hand information and advice by direct talks with parents in their homes. The health camp furnished daily instruction to 40 boys, who not only learn but live health habits during the camp season. The teaching of these boys was continued through the winter in special weekly class meetings at the Y.M.C.A.

Montreal, Quebec — Scholarships were granted by the city administrators in 1931 to two physicians of the Department of Health in order that they might complete their studies in public health at Johns Hopkins. Appointment was made by the city executive committee on the recommendation of the Department of Health Director. In the terms of the grant of \$1,200 to each physician, the appointed physicians are to remain in the city's employment for a period of 5 years, and their leave of absence was granted with salary for the duration of the course. "Such special training of members of the staff will contribute greatly in maintaining the Department of Health of the city on a high standard."

During the convention of the American Public Health Association, held in Montreal in 1931, the foundation of a Public Health Institute in the Province of Quebec was suggested. The proposed plan, with a draft of organization; is published in the annual report of the

department of health in order to explain and stimulate interest in this program for the education and training of public health officers.

In 1931, a campaign of propaganda was inaugurated in an effort to teach mothers the value of breast feeding. Lectures to physicians and nurses of the child hygiene division of the department, and an illustrated poster "mother feed your baby yourself" with a distribution of 25,000 copies, were among the features. Both the poster and publications were distributed through the medium of baby clinics. Immunization against diphtheria was continued, 10,056 children having received three preventive treatments.

Bernalillo County, N. M.—While no cases of typhoid were traced to infected water, milk, or other food, a large number were secondary, developing in homes where inadequate attention was paid to personal hygiene and disinfection of body discharges, according to the 1931 County Health Department report. Multiple cases included in one instance 7 different members of the family who contracted the disease from the original patient.

Tuberculosis cases and deaths decreased considerably in 1930 and 1931, "perhaps due to the fact that economic conditions militated against the individual with tuberculosis migrating to the Southwest in search of climatic advantages."

The budget of \$15,852 gives a per capita expenditure of \$.326 for the year by the County Health Department. There were 107 lectures given with an attendance of 8,417; 1,614 bulletins and 645 circular letters were distributed; 345 newspaper articles on health were printed; and 5 health exhibits were prepared. One of the commendable features of this report is a 2-page statistical summary of 22 major activities, which effectively picture the scope

of services and will be useful for comparative purposes another year as well as for comparison with the work of other departments.

Brantford, Ontario—The annual report of the health officer for 1932 records the use of toxoid for 10 years during which time 10,892 children have been treated. The last case of diphtheria was reported in 1930. An average tuberculosis mortality rate of 22.9 for 3 years is noteworthy. This is less than one-third of the Dominion rate and less than one-half of the rate for the Province. In stressing the importance of health education in fighting tuberculosis, the Deputy Minister of Health is quoted as saying, "Health education is one thing which is extremely important in promoting and stimulating public interest in wiping out tuberculosis." He urged volunteer health organizations to "Spread the gospel of health, draw public attention to articles written on this subject, bring the matter to the people who are governing us, and work on them until they do something about it."

United States Public Health Service—The Surgeon General's report for the fiscal year 1932 notes that "The increasing use of international aerial transportation makes it of special importance that current information relating to the prevalence of disease in foreign countries be available." Cholera was not reported outside of Asia and the adjacent islands. In the Philippine Islands there were 936 cases reported as compared with 4,600 in the previous year. All of the grand subdivisions of the world except Australia reported plague in 1931. In North America no case of human plague was reported. Yellow fever exists in endemic form in extensive regions in Africa and South America. International health agencies recorded 160,000 cases of smallpox,

with 33,000 deaths, as compared with 315,000 cases and 65,000 deaths, the previous year.

The general health of the people of the United States as reflected by mortality rates was maintained at a high level during the past 2½ years.

. . . It is quite probable that the present remarkably good health conditions are, to some extent, the direct result of efforts on the part of health agencies, which have, no doubt, retarded the evil effects of unemployment and economic hardships upon health. The fortunate absence of any serious widespread epidemics has also been a factor.

Regular coöperative rural sanitation studies and demonstrations were conducted in 144 projects in 28 states. The annual survey by the Service showed that on January 1, 1932, there were 616 counties in the United States operating permanent local health service under the direction of a full-time medical health officer, an increase of 59 over the number recorded the previous year.

This comprehensive report deals with the measures carried out for the prevention of the introduction of diseases from abroad, the medical examination of aliens, the prevention of the spread of diseases in interstate commerce, and important investigations of public health problems, including cancer, heart disease, leprosy, mosquito control, pellagra, and many other conditions.

Providence, R. I.—In the 1931 annual report of the Providence Superintendent of Health, attention is properly directed to the 48 years of continuous service, as superintendent, of Dr. Charles V. Chapin, Dean of health officers, who recently retired from this office.

. . . Dr. Chapin is not only a student but also a clear practical thinker, which qualities brought him widespread distinction. Under his leadership, the health department of this city was not merely efficient but a step or two ahead of other cities. The work of the de-

partment has been centered on the things which are most necessary and worth while.

During 1931, there were 1,137 prenatal letters distributed. Six nurses supervise the children delivered by midwives until they are 5 years old, making 14 calls on each well baby before it is 1 year of age, monthly calls during the second year, and 4 calls a year thereafter. One nurse supervises the infants and young children in licensed boarding homes, and the infants of such unmarried mothers as are not under the nursing supervision of private agencies. One nurse from the department makes 1 visit upon each infant delivered by a physician, provided the mother is not on the maternity service of the district nursing association or a ward patient at the Lying-In hospital. Coöperating with the State Children's Bureau, this nurse also visits periodically the licensed maternity homes and some of the day nurseries in Providence. The infant mortality rate was 57.5 for the year.

The school dentist examined the pupils of the second and third grades of 20 parochial and special schools. Of the 2,003 pupils, 1,559 had carious teeth or some other dental defect. Children found in need of treatment by school dentists, physicians, or nurses were referred to their family dentists, but if parents were unable to pay a private dentist, the children were referred to one of 3 hospital or special clinics, or if below the fourth grade, to one of nine public school dental clinics for treatment. The Exchange Club continued to provide dental treatment at home to persons ranging in age from 3 to 21 years who were so physically or mentally handicapped that they could not attend a dental clinic.

Public Health Organization in Indiana—The first regular meeting of the Indiana State Board of Health was

held January 18, 1882. The total appropriation for the first biennial period was \$5,000 per annum. This year the Indiana State Board of Health is celebrating its 50th birthday.

Few health organizations can boast of only 5 administrators over a period of 50 years—an average of 10 years per administrator. This speaks highly for the efficiency of the Indiana organization and its removal from political intrigue. As a matter of fact the State Board of Health has had practically only 3 administrations as the first 2 health officers served but a few months each. Dr. Metcalf served as Secretary from 1884 to 1896. Dr. Hurty, that great pioneer of health promotion, a former President of the American Public Health Association (1912), served from 1896 to 1922, and his successor, Dr. King, is still in command.

At first the State Board of Health devoted its energy to the establishment of local boards of health in counties, cities, and towns throughout the state. A state quarantine law was enacted in 1903 and the laboratory established in 1905. A model housing law was passed in 1912. The present State Health Department is organized with the following divisions: Executive, Vital Statistics, Chemistry (including milk and food), Communicable Disease (including venereal disease), Infant and Maternal Hygiene, Public Health Nursing, Housing and Industrial Hygiene, and Laboratory of Bacteriology. In 1931 the annual appropriation was \$275,000. There are 108 employees, all of whom are full-time except the medical directors in charge of 14 venereal disease clinics.

The first white settlement in Indiana was that of Vincennes and it was here that pioneer efforts were made to improve the health of its citizens. The first health ordinance in Indiana was passed in Vincennes in 1819 prohibiting the creation of nuisances which were

against the public comfort and welfare. It dealt largely with garbage and other offensive matter. The town constable was empowered to remove or cause to be removed all nuisances from the street and penalties could be invoked. This town was visited by an epidemic of yellow fever in 1820. In 1832 Asiatic cholera raised havoc in many communities and other health boards were appointed, especially that at Madison.

It is stated that the first native of what is now Indiana to be vaccinated against smallpox was Little Turtle, a famous Miami Indian Chief. The story goes that he was vaccinated at the time of a visit to Washington where he went to confer with the great White Father.

The first health board in Indianapolis was established in 1850. A public water supply system was constructed in Madison as early as 1816. This bulletin is filled with valuable historical facts concerning the early development of public health administration in Indiana. —*Month. Bull.*, Indiana State Board of Health, Nov., 1932.

U. S. Children's Bureau—During the fiscal year ended June 30, 1932, short, intensive courses in obstetrics (on request of state departments of health and county medical societies) for doctors in active practice, carried on for 2 years through the coöperation of the medical school of Emory University in Atlanta, Ga., were extended to rural communities in Kentucky and Mississippi. Courses are scheduled for New Hampshire.

A special investigation was carried out in New Haven of the value of salmon oil in the treatment of infantile rickets.

If the quantity of salmon oil potentially available in the salmon canning industry were to be put on the market as a properly standardized food and supplied at low cost

through the usual channels for distribution of food, one of the great nutritional needs of children would be more easily and more adequately met.

Ten years ago, it is stated, approximately 121,000 children were receiving aid in the 40 states that then had mothers' aid laws. In 1931 reports from 44 states and the District of Columbia show that approximately 250,000 children were receiving this form of assistance in their own homes. The total amount reported as paid to mothers' aid families during 1931 was approximately \$35,000,000. In 82 per cent of these families, the father was dead; in 5 per cent he had deserted the mother; in 2 per cent the parents were divorced; in 3 per cent the father was in prison; in 4 per cent he was physically disabled, and in 3 per cent mentally disabled.

For the last 4 years the recreation specialist of the bureau has given most of her time to furthering programs in rural districts. This work has been done in coöperation with the extension division of federal and state departments of agriculture, and has reached many groups of older boys and girls and women, and a number of mixed groups of men and women. Last year there was an increase in the numbers of adult groups seeking advice and assistance in planning for leisure-time activities and social life for their communities.

The Children's Bureau, among other activities, has been engaged actively during the last 2 years in the development of the current reporting of local social statistics and centralized tabulation and analysis. Such a plan is necessary to provide for information as to significant national and local trends in social and health services in child welfare and related fields.

LABORATORY

TITRATION OF THE NEUTRALIZING POTENCY OF ANTI-MENINGOCOCCUS SERUM BY THE PHENOMENON OF LOCAL SKIN REACTIVITY*

GRACE M. SICKLES

*Division of Laboratories and Research, New York State
Department of Health, Albany, N. Y.*

A SERIES of tests was undertaken to investigate the possibility of using the measurement of the neutralizing potency by the phenomenon of local skin reactivity¹ as a control upon the method for standardization of anti-meningococcus serum by the agglutination test.

Preliminary tests were carried out by the method of Schwartzman² without "auxiliary antibody." The results confirmed the observation of Schwartzman³ that differences were obtained in the degree of neutralization of filtrates of different strains of meningococci even from the same group.

The sera tested by this method did not appear to be high in neutralizing potency when a serum titrated against a group-III toxic filtrate sent us by Dr. Schwartzman was used for comparison. Clinical reports on lots of serum from two horses from which some of the sera tested were obtained indicated that they were therapeutically effective. Of 30 reports returned on the use of serum from one horse, 25 were of recoveries; of 14 on the use of serum from the other horse, all were of recoveries.

In an attempt to obtain serum of high neutralizing titer, immunization of horses with toxic filtrate together with live culture was undertaken. At the

same time because of the expense involved and in an attempt to control some of the variables in the Schwartzman test, another method of titration was used. Neutralization of various dilutions of a broth-filtrate toxin by the serum to be tested in a series of intradermal injections on the depilated backs of large rabbits was compared with neutralization of the same dilutions of toxin by normal horse serum and by other sera on the same animal. The intravenous injection given 18 hours later was 0.2 per cent agar.⁴

With this technic, differences in neutralization, such as are observed in the simple intracutaneous tests with streptococcus toxin and serum, were also revealed with the meningococcus toxin and serum; and the necessity for reliable standards of comparison before the test will be of value as a method of standardization was clearly indicated. For the present, however, it is of value in permitting direct comparison of the test serum with other sera on the same animal.

When tested by this technic, the method of immunization with live culture intravenously, together with toxic filtrate subcutaneously, apparently produced serum of higher neutralizing titer in one horse than was usually obtained with the routine method of injection with live culture intravenously only. The serum of another animal under immunization by the latter

* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

method, however, was just as high in neutralizing potency.

Clinical reports on the therapeutic value of sera from these horses are not as yet available.

CONCLUSIONS

Titration of the neutralizing potency of antimeningococcus serum by the phenomenon of local skin reactivity is possible within certain limits.

The significance of the test as an indication of therapeutic value has not yet been established but the simpler technic, although not sufficiently developed to be used as a method of

standardization, provides a means for comparison and evaluation and supplies information not obtained with the agglutination test.

SOME VARIANTS OF *BACILLUS MEGATHERIUM**

GEORGES KNAYSI, PH.D.

Department of Dairy Industry, Cornell University, Ithaca, N. Y.

THE variation of *Bacillus megatherium* has been studied in meat infusion broth at pH 6, 7, and 7.8, with and without the addition of lithium chloride. A large number of variants were obtained under different conditions. Some of the most interesting variants came from the alkaline broth. One of these was a pigment forming strain growing in deep yellow colonies. Another was a very heavily capsulated strain in colonies which flow if the Petri dish is tipped at an angle. A third variety gave a thin, translucent colony containing, even before it was 24 hours old, over 30 per cent of shadow cells. A fourth strain, with a similar translucent colony when young, showed an excessive formation of buds at the tip of the cells, where as many as four spherical buds in a chain, reminding one of mold conidia, were observed.

Formation of buds along the side of the cell was less frequent. Sometimes a bud at the tip of a cell would be elliptical with the long axis perpendicular to the long axis of the cell. Such buds were isolated in micro-droplets and found to grow into rods which multiplied. Many of the spherical buds and the elliptical ones were very actively motile and showed flagella similar to those of the cell from which they originated. This strain was non-capsulated and no spores were seen in hundreds of cultures in micro-droplets, where normal strains sporulated very profusely. Aside from budding, this strain formed, even in young colonies, an unusual number of peculiar cell forms similar to what has been described in the literature as arthrospores, microcysts, etc. Many of these peculiar forms were actively motile.

Other interesting variants have been isolated, but have not yet been studied in detail.

All of these variants can be kept

* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 27, 1932.

stable by frequent plating, and all of them tend to change in old colonies and old liquid cultures.

The colonies of *Bacillus megatherium* show regular cyclic changes, common to the parent culture and to all of the variants. These cyclic changes consist in the formation of concentric translucent and opaque zones. Depending on the variant, the center of the colony may be opaque or translucent. The translucent rings contain mainly shadow cells, some spores, and other forms. The opaque rings are made up of cells of normal appearance and cytology.

In about 3 days or more secondary growth can be seen in the form of opaque pimples over the area of the whole colony and sometimes as outer rings or extensions of various shapes of the margin of the colony. The secondary colonies follow similar transformations to those of the parent colony and may give rise to tertiary colonies. When secondary colonies are cultured, they usually reproduce the parent strain. However, the yellow strain forms white secondary colonies with a yellowish

tinge giving rise on further cultivation to colonies of the same color and to the yellow colonies of the parent strain. Sometimes the secondary growth is too dense and continuous, and pimple-like colonies appear after a long incubation. This probably represents a tertiary growth.

When the colony becomes very old, the primary growth almost entirely disappears, and the faint area of the colony shows most evidently the small, pimple-like secondaries.

An attempt was made to study the sequence of variants from a given initial type. In some cases a sequence has been demonstrated, while in other cases no regularity has yet been discovered.

A daily transfer of the culture in dissociation experiments has been found to result in the selection of certain types which grow best under the given conditions. Aging of cultures which for a long time gave only the same types when frequently transferred, resulted in the appearance of a variety of other forms.

VITAL STATISTICS

Vital Statistics for Rhode Island—1932—Preliminary figures on file in the Public Health Commission of Rhode Island, show a birth rate for the state in 1932, of 15.7 per 1,000 population, a marriage rate of 5.7 per 1,000, and a death rate of 11.6.

The filing of late returns for births and marriages will change the birth and marriage rates slightly, but not sufficiently to be of significance. The few deaths that occurred in 1932 too late for filing before the new year will make little if any change in the death rate.

The birth and marriage rates are the lowest recorded in Rhode Island since 1855. In spite of a steady increase in

population amounting to over 55 per cent since 1902, the actual numbers of births (11,061), and marriages (4,048) are the lowest in the past 30 years. While the depression has undoubtedly played a part in the declining marriage rate, which is reflected in the birth rate, the depression has only accelerated a downward trend in marriages and births which has been evident during the past 10 years.

The death rate for 1932, of 11.6 is the second lowest death rate recorded for Rhode Island since 1855. Only for the year 1931, when the death rate was 11.4, was the record better. The increase of two-tenths of a point in the

rate for 1932 over 1931 is due to a slight increase in deaths during November and December as compared with the corresponding months of 1931. During the first 10 months of 1932 the death rate was the same as for the corresponding period of 1931.—Births, Deaths and Marriages Recorded in Rhode Island During 1932. Released January 5, 1933.

Birth Rates and Fecundity in Italy

—The annual number of births of living children in Italy increased in the 19th century until it reached 1,152,906 in 1887. Thereafter it declined gradually until it was 1,042,090 in 1903. There was a gradual decline to 1,040,000 in 1928, the lowest it has been in normal (non-war) years since 1887. But the decline in other European countries is even greater. The deaths in Italy reached a maximum of 869,992 in 1880, decreasing to 635,788 in 1912, rising to 1,240,425 in 1918, but decreasing to 611,362 in 1927. In 1887 the excess of births over deaths was 323,914, and in 1928 it was about 426,000. In Poland this excess was 427,366, in Germany 404,699, in Spain 216,167, in Great Britain 200,405, in France 65,042 in 1927. In 1927 Italian fecundity was 30 per cent inferior to the level of 1866–1875.

The fecundity of legitimate births was 26 per cent lower and that of illegitimate births was 50 per cent lower in the same period of comparison. Illegitimacy has diminished in Italy until it comprises less than 5 per cent of the births. This decline may be due to greater precautionary measures rather than to increased sexual morality. Italy has a legitimate fecundity rate of 214 per 1,000 marriages in the fertility period as compared with the French rate of 139, the English of 133, and the German of 128. In 1926, the Italian birth rate was 27.2, the death rate 16.9, leaving an excess of birth over

death rate of 10.3. The birth rate in various Italian provinces varies between the low British and the high Japanese rate. The death rate varies between the low British and the high Russian. The gain in births over deaths varies between the low French and the high Polish and Japanese rates.—L. L. Bernard—Mortara, Giorgio. *Natalità e urbanesimo in Italia*. I. *Nuova Antologia*. 64, 1374:485–496 (June 16), 1929. *Social Sci. Abstr.* 4:2080–2081 (Dec.), 1932.

Mortality in the Industrial Population, 1932—In no previous year has the health record of the industrial populations of the United States and Canada equalled that of 1932. This is clearly indicated by the mortality experienced by the many millions of industrial policy holders of the Metropolitan Life Insurance Company. Their death rate for the year was at the unprecedented figure of 8.34 per 1,000 living, at ages 1 and over—lower by a narrow margin than the previous minimum of 8.37, registered in 1930.

New minima were recorded for 9 important causes of death, namely, typhoid fever, measles, whooping cough, diphtheria, pneumonia, tuberculosis, diarrheal diseases, conditions incidental to pregnancy and childbirth and accidents. Furthermore, among the various types of accidental death, new minima were recorded for accidental burns, machinery accidents, and drownings.

Based on what has happened among these insured wage-earners and their dependents, it is safe to say that the death rate of the general population, in 1932, was also at a new low point. The mortality rate of this large group of insured persons has always proved to be an accurate index of health conditions in the general population—both in the United States and Canada—the mortality statistics for which do not

become available until approximately 1 year after it is possible to publish the figures for the insured group.

The 1911 death rate among Metropolitan industrial policy holders, at ages 1 and over, was 12.5 per 1,000. Had this death rate of 21 years ago prevailed again in 1932, nearly 70,000 more of this insured group would have died than the 139,491 who actually did die during the year. In 1931 alone this net saving amounted to 32,000 lives of policy holders and the accumulated saving since 1911 is over 464,000 lives.

The expectation of life, at birth, among Metropolitan industrial policy holders for the year 1931 was 57.90 years. This may be compared with an expectation of 46.63 years in 1911-1912, a gain of 11.27 years during the two decades. This corresponds to a gain of 24.2 per cent in the average life span of the industrial policy holders. In the general population, in approximately the same period, the gain was only 6.66 years. Thus the improvement among the insured wage earners and their dependents has been almost twice that for the population at large.

It is a matter of great interest that the expectation of life of the industrial population is now within 2 years of that of the general population. Twenty years ago, there was a difference of $6\frac{1}{2}$ years in favor of the general public. In other words, working men and their families have shown a marked improvement in their vitality. This is due, for the most part, to considerable decreases in the mortality at all of the younger ages of life, because the preventable diseases have been brought, to a marked degree, under control. Few realize the enormous social and economic benefits which these gains have brought about.

The outstanding public health fact of the year was the reduction of the tuberculosis death rate from 76.2 in 1931 to 69.8 in 1932, a new low point. The drop in a single year was 8.6 per cent,

the greatest year-to-year decrease in a decade. The improvement among insured negroes was even greater than for the whites. The tuberculosis death rate has now reached 70 per 100,000. The decline in the mortality from tuberculosis in a single year effected a saving of 1,100 lives in 1932 alone.

The death rate for the 4 principal communicable diseases of childhood has dropped exactly 50 per cent in 4 years, and almost 70 per cent in 10. The death rate for each of these diseases, except scarlet fever, is the lowest ever recorded; and that for scarlet fever is one of the lowest. Even diphtheria, to which the chief interest attaches, has become a minor cause of death. It promises soon to be so entirely out of the picture that no place need be assigned to it in the statistical tables.

The mortality rate for pneumonia dropped in 1932 to a new minimum of 56.8 per 100,000, a decline of 8.5 per cent from the previous low point recorded in 1931. Both white and colored policy holders shared in the improvement.

Despite the country-wide outbreak of influenza in December, the year closed with a mortality rate for influenza of only 17.6 per 100,000, which is well below the average for the last 10 years.

Deaths from conditions arising out of pregnancy and childbirth have shown a practically continuous decline among insured women over a period of 12 years. The puerperal death rate of 1932 (10.6 per 100,000) is about half that recorded for the first few years of the decade beginning with 1920. Nevertheless, crude death rates are misleading as a gauge of developments in the mortality connected with childbirth. The drop is due, in part, to the declining birth rate, whereby women have been exposed less frequently to the hazards of childbirth. The ratio of puerperal deaths per 1,000 live births is a much better measure of what has happened.

But, unfortunately, it is not possible to give this more accurate measure for maternal mortality in this industrial insurance experience. In the general population, where birth data are available, the puerperal death rate per 1,000 live births has shown but little variation from year to year, and is far higher than it need be. It is double the figure which prevails in Denmark and 50 per cent above that in England and Wales. It has been estimated that nearly two-thirds of the deaths which occur could be prevented if expectant mothers received the type of care made available by certain agencies which have concentrated on the care of pregnant women.

Since 1929 there has been a distinct and continuous decline in the alcoholism death rate. In that year it was 3.5 per 100,000; in 1932 it was only 2.4, the lowest figure recorded among Metropolitan industrial policy holders for 10 years. On the other hand, the rate for cirrhosis of the liver, which is often of alcoholic origin, has shown a slowly rising tendency in recent years.

The 1932 mortality record was distinctly unfavorable for 3 diseases, which recorded new maximum death rates. These are cancer, diabetes, and diseases of the heart. A definite upward trend has been manifest for each over a long series of years.

The most disquieting development of 1932 was another sizeable increase in the mortality from cancer. This amounts to 7.8 per cent in a single year, and to 15.8 per cent in 2 years. There has been, for several decades, all over the world, a slow but persistent rise in the cancer death rate; but it is difficult to assign a reason for the sharp acceleration of the last 2 years among insured wage earners. With the exception of diabetes, no increase of equal magnitude has been in evidence for any disease. Whether the population at large has experienced a similar rise cannot be determined at this time. Such

fragmentary data as are available indicate that it has not, although the increase in 2 years appears to have been greater than the average during the last decade. Among the insured, there has been a shift in the relative age distribution whereby a somewhat larger proportion than formerly is now in the higher age ranges where most of the deaths from cancer occur. This alone would bring about an increase in the crude death rate, not only for cancer but for the several "degenerative" diseases. If, however, this had been the sole cause for the rise in the cancer mortality rate, we would have experienced corresponding increases in the rates for cerebral hemorrhage, chronic nephritis, and heart diseases. Such increases have not been observed. The rises in 1932 for cerebral hemorrhage and chronic nephritis were negligible, and that for heart disease amounted to less than 5 per cent in that year, and to only 7 per cent in 2 years. The unprecedented increase in cancer deaths, among the American wage earning population, has attracted attention all over the world. One commentator suggests that it may be related to an increasing hesitancy to call for medical and surgical aid when the patient and his family are without means to pay for it.

Had the much lower cancer death rate of 21 years ago prevailed in 1932, 4,026 fewer Metropolitan industrial policy holders would have died of this disease than the 15,394 who actually died during that year. Had even the rate of 1931 prevailed, 1,117 fewer lives would have been lost.

The previous high point for diabetes was 21.4 per 100,000, in 1931; and the rise, in 1932, was to 23.3, or 8.9 per cent. The increase in only 2 years has amounted to practically 25 per cent. The death rate for this disease has now risen continuously for 8 years.

There are, nevertheless, certain encouraging aspects in the problem of

diabetes. Despite the rapidly rising death rate, diabetics are living longer today than ever before. The average duration of their lives from the onset of the disease, to death, has increased materially since the discovery of insulin. Recent investigation has shown that the death rate has declined among persons under 45; but among older people, particularly among women, the rate has increased. It is in these older age ranges that the incidence of the disease is highest; and here the rise in the death rate has more than counterbalanced the drop in the younger age groups.

The mortality from heart disease, the leading cause of death since 1922, continued to mount, in 1932, with the rate reaching the new high point of 157.4 per 100,000. This is a rise of 4.9 per cent from the previous maximum recorded in 1931 and of 11 per cent, as compared with the figure for 1911. Since 1919, there has been a decided upward trend in the cardiac disease death rate, although the increase has been by no means continuous.

The one bright spot with respect to the heart disease mortality record is that the rate is declining at the younger ages. This means that such items as school medical inspections, industrial hygiene, and other preventive efforts against heart disease are bearing fruit; for, while heart conditions usually cause death late in life, they often begin in childhood or adolescence. As cases of diphtheria, the other infectious diseases of childhood, tonsillitis, dental diseases, and other focal infections become fewer,

cardiac impairments at the younger ages may be expected to decrease in number.

The death rate for all kinds of accidents combined was lower in 1932 than ever before. This reflects, primarily, the drop during that year in industrial activity, in transportation, and more particularly in automotive traffic, both pleasure and commercial. The decrease in automobile fatalities, as compared with 1931, amounted to 14 per cent.

Three types of accidents recorded lower death rates in 1932 than ever before, namely, accidental burns, machinery accidents, and railroad accidents.

The rise in the suicide death rate in 1932 was less than 6 per cent, a smaller year-to-year increase than has been observed in a number of previous years. The facts concerning suicide show clearly that the rise in the death rate, since 1929, is not entirely chargeable to the unfavorable economic conditions which have prevailed during the last 3 years. There has been a continuation of an upward trend that has been in evidence since 1925—over a period which includes some of the most prosperous years in the history of the country. Furthermore, the suicide situation has improved materially in two decades. For the last year, 10.8 Metropolitan industrial policy holders in every 100,000 took their own lives, whereas in 1911 suicides accounted for 13.3 deaths per 100,000.—*Stat. Bull. Met. Life Ins. Co.* 14:1-8 (Jan.), 1933.

PUBLIC HEALTH ENGINEERING

SHELLFISH TREATMENT PLANT AT NEWBURYPORT, MASS.

EDWARD WRIGHT

Sanitary Engineer, Massachusetts Department of Public Health, Boston, Mass.

FOLLOWING an extensive examination in 1925 of the Massachusetts tidal waters and the shellfish therein, the State Department of Public Health closed to shellfishing many thousands of acres of shellfish producing areas. This action caused considerable distress in many localities where shellfishing was an important industry, especially in the city of Newburyport where some 3,000 acres of flats were declared to be contaminated.

The department has since carried on extensive studies and experiments under the direction of H. W. Clark, Chief Chemist, and Edward Wright, Sanitary Engineer, Massachusetts Department of Public Health, with a view of finding some practical method for the purification of shellfish. It was found that transplanting into clean waters was impracticable when applied to soft shell clams. Therefore, experiments were begun with the use of chlorine. An experimental plant was subsequently established in Newburyport and operated successfully for several months, under varying temperatures.

The present municipally owned plant at Newburyport was built by the city in 1930. It is located at the northern extremity of Plum Island at the entrance to Newburyport Harbor and it is a single story wooden building consisting of a tank room, laboratory, receiving room, and a shipping platform.

The tank room is 50' by 30' in plan

and contains 8 concrete tanks. The cast-iron sea water intake pipe is about 120' long and 4" in diameter. Water is pumped on the incoming tide only by means of a centrifugal pump having a

*Newburyport Shellfish Treatment Plant—
Laboratory and Shipping Platform—
(Note boxes used at the plant)*

rated capacity of 350 gal. per min. and driven by a 10 H. P. motor. There are also 2 air blowers, each having a capacity of 54.5 cu. ft. per min. and driven by a 5 H. P. motor. Each tank is 16' long, 5' wide and 5' deep, and capable of holding about 35 bbl. of clams. The tanks are provided with 4" inlet pipes and 6" outlets and two 1" galvanized iron perforated air pipes near the bottom of the tank.

Upon arrival at the plant the clams are "culled" over to remove all dead or damaged shellfish and then they are placed in boxes of wood and wire construction holding about $\frac{1}{2}$ bushel each. Before being placed in a tank the raw clams are washed in sterilized sea water and the same process is repeated at the end of the treatment. As sea water is

pumped into the tank a sufficient quantity of sodium hypochlorite solution is added to sterilize the water. During the treatment period smaller quantities of chlorine are added at 2-hour intervals until the residual free chlorine is brought up to about 0.3 or 0.4 p.p.m. It has been found that chlorine if present in excess of 0.5 p.p.m. would interfere with the natural functioning of the clams upon which the purification process depends. To replenish the oxygen consumed by the clams, air is blown intermittently in the tank, which also helps to obtain a more uniform diffusion of chlorine.

Samples of raw and treated clams of each lot are tested daily in the laboratory of the plant. All shellfish are treated for at least 24 hours, and, in case the raw scores are found to be 140 or more, longer treatment periods are required.

All shellfish are dug and transported to the treatment plant under the supervision of deputy wardens appointed by the State Supervisor of Marine Fisheries, and daily receipts, as well as weekly reports, containing information regarding quantities of shellfish dug, areas dug from, etc., are mailed to the Supervisor of Marine Fisheries and duplicates to the Department of Public Health. Daily reports of the bacteriological and chemical laboratory at the plant are mailed to this department, giving the results of bacterial tests of the raw and treated product. The operation of shellfish treatment plants is controlled by the State Department of Public Health under authority of Chapter 235 of the Acts of 1930, which provides that all such plants shall be approved in writing by the Commissioner of Public Health as to the location, construction, and operation thereof, and as to the person in immediate charge thereof.

The law also provides that the commissioner may revoke the approval of

the plant at any time, and it authorizes the department to promulgate rules and regulations. Such rules and regulations have been drawn up, and the operation of the plant is checked up regularly to see that it is operated in conformance with the said rules and regulations. Samples of raw and treated shellfish are collected frequently and tested at the state laboratory.

*Newburyport Shellfish Treatment Plant—
Tank containing clams in process of
purification*

The operation of the shellfish treatment in plants in Newburyport and elsewhere has proved beyond doubt the practicability of purifying shellfish by means of chlorine. As a result, large clam growing areas have been reclaimed and work has been provided for hundreds of men.

A copy of the rules and regulations under which this and other similar plants are operated follows. Shellfish treatment plants have been established subsequently at Plymouth and Scituate but the Newburyport plant is the only one now in operation. These plants appear to be a financial success when the clam business is good.

The writer has charge of shellfish in-

vestigations, and supervision of treatment plants. He is assisted in this

work by A. C. Bolde who collaborated in preparing this article.

RULES AND REGULATIONS RELATIVE TO THE OPERATION OF PLANTS FOR THE TREATMENT OF SHELLFISH PROMULGATED UNDER THE PROVISIONS OF ACTS OF 1928, CHAPTER 323, ACTS OF 1929, CHAPTER 372 AND ACTS OF 1930, CHAPTER 235

Adopted by Massachusetts Department of Public Health on March 8, 1932

1. All shellfish treatment plants shall be kept under adequate supervision by a qualified chemist or bacteriologist at all times, and no shellfish shall be taken therefrom until passed by the person in charge after treatment as provided in the following rules and regulations:

2. The person in immediate charge of a shellfish chlorinating plant shall send a detailed description in writing to the Department of Public Health of all areas from which it is proposed to take shellfish for treatment purposes at least 1 week before shellfish are to be taken therefrom. Upon taking shellfish from a contaminated area under a written permit from the Supervisor of Marine Fisheries the person holding the said permit shall forthwith deliver the shellfish so taken to the person in charge of the treatment plant or his assistant and receive a receipt therefor either as to the quantity or weight, and as to the date and hour of delivery. Duplicate receipts shall be forwarded weekly to the Department of Public Health.

3. Storage compartments shall be provided for untreated shellfish, and all such shellfish shall be kept wholly separate from treated shellfish. The said compartments shall be under the supervision of the person in charge of the plant. A separate entrance shall be provided for the untreated shellfish. All shellfish shall be handled and stored under such conditions as will keep them alive.

4. All shellfish shall before treatment be thoroughly washed or hosed either with sterile sea water or water from some other source approved by the department, until all foreign matter is removed. All shellfish shall again after treatment be thoroughly washed or hosed with water taken from a source approved by the Department. In washing or dousing the shellfish in chlorinated water, the water shall contain throughout this process at least 0.5 p.p.m. of available chlorine.

5. All shellfish shall be thoroughly culled or inspected before filling the containers used for treatment purposes, and all shellfish shall again be thoroughly culled or inspected after treatment. All dead shellfish or shellfish in broken or cracked shells shall be destroyed.

6. Containers used in the treatment process

shall be filled under the supervision of the person in immediate charge, and the containers shall not be filled with shellfish to a depth of more than 8 inches. In filling the containers a clearance of at least 1 inch shall be left between the upper layer of shellfish and the upper rim of the container. Containers used for treatment purposes shall not be used for any other purpose, and no containers or other equipment used on the flats shall be placed in the treatment tanks.

7. When shellfish are taken from several contaminated areas for treatment purposes, those taken from each separate area shall be treated in separate treatment tanks and shall not be mixed with shellfish from other areas.

8. All water in shellfish treatment tanks shall be subjected to chlorine treatment, and no shellfish shall be passed until the same have been treated for at least 24 hours, and for a longer period if the scores of the raw shellfish are 140 or over, in water which shall have been sterilized by chlorine and contain at least 0.5 p.p.m. of available chlorine 15 minutes after application, and the water shall be maintained in a reasonably sterile condition throughout the entire treatment period. Each treatment tank shall be filled with sea water from the usual source at least twice during the treatment period of each lot of shellfish. Determinations of the amount of dissolved oxygen in the water in the treatment tanks shall be made in order to ascertain that oxygen to the extent of at least 30 per cent of saturation is always present. Two or more samples of each lot of raw shellfish and four or more samples of each lot of treated shellfish shall be examined by the Standard Methods of the American Public Health Association for the determination of the *B. coli* score. Records containing the following information shall be available at the treatment plant at all times:

- a. Area where shellfish were dug
- b. Quantity of shellfish in tank
- c. Time of starting treatment.
- d. Time of ending treatment
- e. Scores of shellfish before treatment, as soon as available
- f. Scores of treated shellfish, as soon as available

- g. Time and quantities of chlorine applied
- h. Available chlorine determinations
- i. To whom sold

No shellfish shall be removed from the treatment tanks until the 24-hour results of the untreated shellfish are read.

9. The results of the analyses of all samples, signed by the bacteriologist, shall be sent by mail to the Department of Public Health on each day that the plant is in operation.

10. Treatment plants shall be used for no purpose other than the handling of shellfish, and no shellfish from clean areas shall be handled at a shellfish treatment plant or by the management of such a plant. Material foreign to this particular business shall not be stored within the plant. No person not an employee of the shellfish treatment plant or a representative of the Department of Public Health or Department of Conservation shall be allowed access to the treatment plant or to the laboratory except by permission of the person in charge. All shellfish treatment plants shall be provided with suitable toilet facilities.

11. A portion of the plant may be used for shucking purposes, and the operation of this portion of the plant shall be under the supervision of the person in charge of the

plant. Such a shucking plant shall be constructed and operated in general accordance with the U. S. Public Health Service Minimum Requirements for approval of State Shellfish Control Measures and Certifications for Shippers in Interstate Commerce.

12. Only clean containers shall be used for shipping treated shellfish in the shell. If bags are used for this purpose all such bags shall be sterilized before being used. Only non-returnable, clean containers shall be used for shipping shucked shellfish.

13. If the shellfish are shipped from the plant in the shell, the shipping containers shall be suitably sealed and marked as "Passed. shellfish treatment plant." If the shellfish are shucked at the plant, the shipping containers shall be suitably sealed and marked as "Passed and Shucked shellfish treatment plant."

14. All other rules and regulations prepared by this department or by the Supervisor of Marine Fisheries of the Division of Fisheries and Game relative to shellfish shall be followed in the operation of all shellfish treatment plants. The Department reserves the right to change the above rules and regulations from time to time as occasion may require without notice.

THE OXIDATION POTENTIAL CONCEPT OF CHLORINATION *

F. C. SCHMELKES

Wallace & Tiernan Co., Newark, N. J.

MEASUREMENTS were presented of the oxidation potential in solutions of hypochlorous acid, chloramine, monochloroglycine and Azochloramide. These measurements were compared with measurements of the rate of bacteria removal. The oxidation potential and bactericidal properties of chlorine were found to run parallel. Any changes which diminish bactericidal

velocity also diminish the oxidation potential, and *vice versa*.

Attention was drawn to the failings of the orthotolidin test as the reagent reduces the pH of the solution to be measured, due to the large amount of hydrochloric acid in the reagent, and thereby increases the oxidation potential to a high value. This test essentially measures the amount of chlorine which can be converted into bactericidal and sterilizing chlorine by lowering the pH. The test therefore does not distinguish between chlorine

* Abstract of paper read before the Public Health Engineering Section and Conference of State Sanitary Engineers at the Sixty-first Annual Meeting of the A. P. H. A., at Washington, D. C., October 24, 1932.

compounds of high and low oxidation potential.

Attention is drawn to the fact that in the ammonia-chlorine process advantage is deliberately taken of the reduction of the oxidation potential to prevent combination of chlorine with phenols, to prevent oxidation of organic matter thus increasing persistency of

the residual, and that this is being done at the expense of bactericidal velocity.

A motion picture was presented, showing the slow death, cessation of movement, agglutination, and disintegration of typhoid bacteria, brought about by treatment with low potential chloramine compounds.

INDUSTRIAL HYGIENE

Division of Occupational Diseases, Connecticut, Annual Report, 1931—This *Annual Report* of the Connecticut State Health Department, 1931, carries 52 pages devoted to the Division of Occupational Diseases, headed by Dr. Albert S. Gray.

During the course of the year, 391 cases of occupational diseases were recorded, only 141 of which, however, were reported by physicians. "Occupational disease is almost entirely preventable, yet it is now costing Connecticut industry millions a year in decreased production, compensation, and medical claims."

There is a discussion of the health relationships of dust, fumes, gases, and toxic materials, ventilation, illumination, sanitary facilities, industrial fatigue, maintenance and supervision. During the year the division made a total of 267 field trips, including 72 surveys of plant conditions. A code is used to classify both hazards and industrial pursuits.

Special studies were made of: (1) soapstone dust exposure, which showed that workers were exposed to an excessive amount of dust; (2) dust hazards of sandblasting; (3) dustiness in wood working operations associated with both dermatitis and pneumoconiosis; (4) foundry dust; (5) lead exposure in brass foundries, which showed that lead present in dust samples was

well below the amount that would constitute a lead hazard as defined by the A.P.H.A.; (6) mercury poisoning, in which it was concluded that the average individual would develop symptoms under the conditions found within a period of several months; (7) carbon monoxide, in which it was found that this gas frequently exceeded toxic limits; (8) exhaust ventilation of spray coating booths, where low velocities were found which might result in poisoning; (9) carbon tetrachloride in dry cleaning in which the discussion relates principally to methods of estimating low concentrations—0.16 per cent being taken as the lower toxic limit; (10) a method for determining benzol vapors; (11) simple preventive measures in connection with dermatitis from soap solution and from cyanide hardening operations; and (12) suggested regulations concerning fumigation with cyanide gas.

There is also a brief review of the Eastern Interstate Conference on Labor Legislation called in June, 1931, by Governor Pinchot of Pennsylvania, and held in Harrisburg. The division likewise carried on various educational activities, held an industrial hygiene exhibit at the New Haven Industrial Exhibition, and entertained a number of foreign visitors. A list is given of the occupational diseases reported, by cause and compensability. E. R. H.

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Venereal Disease Control the Country Over—What official and voluntary agencies attempted during 1932 is recounted state by state. The outstanding conditions seem to be: heavy clinical burdens, reduction in support, and determination in face of discouragement.

ANON. With the States and Communities in 1932. *J. Soc. Hyg.* 19, 2:52 (Feb.), 1933.

Toxin vs. Virus—The findings of a report of interesting research include: diphtheria toxin added to vaccine virus exerts a deterrent action upon "take" and systemic response in rabbits; the action of the toxin is neutralized by antitoxin; and the site of a positive Schick test is insusceptible to vaccine virus for three weeks.

ARMSTRONG, C. Modification of the Vaccine Response in Rabbits by the Application of Diphtheria Toxin to the Vaccination Site. *Pub. Health Rep.* 48, 1:1 (Jan. 6), 1933.

When Babies Refuse the Quart a Day—Two delicious excerpts from this delightful paper: "There is too much competition in weight-gaining during infancy and childhood, and this one fact gives the child the whip hand throughout its young life. It does not take a child long to sense that fat babies and thin mammas are the style." And, "Meal time should be a happy, quiet time. A mad cabaret with one or more of the family acting as whirling dervishes has no place at the child's meal time."

ARNOLD, D. P. Why a Child Refuses to Eat. *New York State J. Med.* 33, 1:20 (Jan. 1), 1933.

Do Public Dumps Menace Health?—This British sanitarian views with alarm "tipping" (euphonic synonym for our "dumping") because

cloths used by syphilitics might lie in the dumps. "I cannot imagine," he shivers, "any more unjustifiable risk than is contained in this particular alone to public health." This seems to us to be the height of something-or-other.

BALDWIN, H. B. C. Disposal of House Refuse. *J. Roy. San. Inst.* 53, 7:359 (Jan.), 1933.

Limitations of Health Yardsticks—Graphs depicting the decline in general and particular death rates are included in this paper which confesses the decided limitations of the general statistical measures of the public health.

BRITTEN, R. H. Trends of Health in the United States. *Pub. Health Rep.* 48, 2:27 (Jan. 13), 1933.

Our Public Enemies—First come the quacks, says this author, the Christian Science healer, the chiropractors and naturopaths; then the anti-vaccinationists, but the greatest menace of all are the anti-vivisectionists. This is an excellent paper, though the author neglects to pay his compliments to the fundamentalists who insist that the youth of our land be taught science a la revelation.

CANNON, W. B. Enemies of Society. *Sci. Monthly*, Feb., 1933, p. 150.

Voice Crying in Wilderness—These are serious conclusions: hospitalization of maternity cases increases, but puerperal mortality does not decrease; meddlesome midwifery and puerperal infections seem to be the major causes; something is wrong with maternity wards in general hospitals; architectural and administrative isolation is needed.

DELEE, J. B. and SIEDENTOPF, H. The Maternity Ward and the General Hospital. *J.A.M.A.* 100, 1:6 (Jan. 7), 1933.

When Colons Disfunction—Glib “health educators” who broadcast cure-all diets for preventing constipation would do well to ponder over this meaty discussion of the disfunctioning colon.

JORDON, SARA M. The Unstable Colon and Neurosis. J.A.M.A. 99, 27:2234 (Dec. 31), 1932.

New Angles of Venereal Disease Prevention—Venereal disease control problems as viewed today suggest only minor changes in program emphasis to meet modern conditions. The recommendations of this able paper are: treatment facilities at high efficiency level to meet increased demand; community measures to meet the needs of the new nomads; recognition of effect of poverty on the family.

KEYES, E. L. The Present Status of Venereal Disease Prophylaxis—Social and Medical. J. Soc. Hyg. 19, 1:1 (Jan.), 1933.

Is There a Polio Susceptible Body?—Fifty-two little poliomyelitis patients were compared with controls in respect to physical characteristics. No evidence of a direct relation of certain characteristics to susceptibility to poliomyelitis was discovered. Draper's findings were not confirmed.

LEVINE, M. I., *et al.* Relation of Physical Characteristics to Susceptibility to Anterior Poliomyelitis. J.A.M.A. 100, 3:160 (Jan. 21), 1933.

Knocking Some Props From Under Contraception Statistics—Women who have been delivered in eastern hospitals are being asked by their medical attendants about their contraceptive practices. Of the white women, 36 per cent use some means, a smaller proportion than is commonly assumed. Later reports will give more detailed findings, but there is much food for speculation here. For instance, this finding: with contraception as actually practiced, there was a reduction in the pregnancy rate under 20

per cent below that which obtained in the group not resorting to this procedure—not a high degree of effectiveness.

PEARL, R. Preliminary Notes on a Coöperative Investigation of Family Limitation. Milbank Quart. Bull. 11, 1:37 (Jan.), 1933.

Catching Bedbugs in Molasses—Health workers who meet the bedbug problem in all its ugliness will want to know the latest wrinkles. This British genius has invented a “trench trap” which is placed all around the infested room. The trench is filled with treacle in which the bugs proceed to drown themselves.

MILLARD, C. K. Presidential Address on an Unsavory But Important Feature of the Slum Problem. J. Roy. San. Inst. 53, 7:365 (Jan.), 1933.

Debunking Posture—“But posture is said to be related to health, to mentality, and to morality. This being the case, it is somewhat confusing to find very delicate and stupid and immoral subjects at the A end of posture distribution, and very vigorous, bright, and honorable children at the D side.

“Even if mentality and morality and health *did* depend on carriage and they are subject to change from what is called poor to better posture, they must relapse with it when the spine returns to its usual curvature, as it apparently always does.”

ROGERS, J. F. The Long and the Short of the Carriage Business. Health and Phys. Ed. 3, 10:11 (Dec.), 1932.

Poliomyelitis Streptococcus and Convalescent Serum—It must be trying to the pundits, who assert that Rosenow's poliomyelitis streptococcus just doesn't exist, to have it continue as the subject of researches, all of which seem to indicate that the condemned microörganism is very much alive. This paper reports the effect of convalescent serum upon the streptococcus.

ROSENOW, E. C. A Specific Reaction of Convalescent Serum on the Streptococcus Isolated in Studies of Poliomyelitis. *J. Immunol.* 33, 6:455 (Dec.), 1932.

Who Teaches Health in Boston?—The many agencies doing health education in the City of Boston are reported upon. Their very number and diversity of interests are eloquent of the need for some coördinating organization. A lesson here for all.

PARSONS, R. I. and TURNER, C. E. Health Education in the City of Boston. *New Eng. J. Med.* 208, 1:19 (Jan. 5), 1933.

Almoners in British Hospitals—Almoner, it seems, is the name hit upon by our British cousins to designate the job of hospital social worker. The chief difference from our h.s.w.'s seems to be that appointee must be a "lady" as understood in its old-fashioned sense."

TELLING, W. H. M. The Rôle of Hospital Almoners in the Maintenance of Health and the Avoidance of Disease. *J. State Med.* 41, 1:21 (Jan.), 1933.

The Doctor Looks at Statistics—Of about 1,400 cases in Baltimore families in this study, nine-tenths exhibited coryza, two-thirds had cough,

nearly half had sore throat, about a fourth were in bed. Three colds per year per person was the mean.

VAN VOLKENBURGH, V. A. and FROST, W. H. Acute Minor Respiratory Diseases Prevailing in a Group of Families Residing in Baltimore (Md.), 1928-1930. Prevalence, Distribution, and Clinical Description of Observed Cases. *Am. J. Hyg.* 17, 1:122 (Jan.), 1933.

Experience With Whooping Cough Vaccine—Of 300 children immunized with pertussis vaccine, 8 were certainly exposed and 127 probably exposed to whooping cough infection. None contracted the disease. The authors warn against stock vaccines.

SAUER, L. Whooping Cough. *J.A.M.A.* 100, 4:239 (Jan. 28), 1933.

And Still We Die From Appendicitis—"If appendicitis is increasing, as is possibly the case, why is not a share of the solution of the problem one of preventive medicine?" The answer to this purely rhetorical question is that the public must somehow learn that delay and improper medication, especially catharsis, invite mortality. Incidentally, most physicians also have something to learn about appendectomy.

WALKER, I. J. A Comparative Mortality Study of Acute Appendicitis. *New Eng. J. Med.* 208, 3:113 (Jan. 19), 1933.

NEWS FROM THE FIELD

"THE LAWYER AND HIS PUBLIC"

A SERIES of radio broadcasts is being offered under the joint auspices of the American Bar Association and the National Advisory Council on Radio in Education. The general subject of the series will be "The Lawyer and the Public," non-technical in nature, and will include 15 broadcasts given by leading members of the legal profession. The broadcasts will be 15 consecutive Sunday evenings, 6:00 to 6:30 Eastern Standard Time, and will be given over a nation-wide network of the Columbia Broadcasting System.

YELLOW FEVER VOLUNTEER DIES

THE death of Paul Hamann, of East Moline, Ill., one of the volunteers in the yellow fever experiment in Cuba in 1900-1902, has been reported. He died of broncho-pneumonia following influenza after an illness of one week. Mr. Hamann was one of the 15 living volunteers who received gold medals and pensions of \$125 per month authorized by Congress in 1929. The medals were presented in 1931.

PRIZE FOR ESSAY ON GOITER

THE American Association for the Study of Goiter again offers \$300 as a first award and 2 honorable mentions for the three best essays based on original research work on any phase of goiter, to be presented at its annual meeting in Memphis, Tenn., May 15-17. Competing manuscripts must be in English and submitted to Dr. Julius R. Yung, 670 Cherry Street, Terre Haute, Ind., not later than April 1. Manuscripts arriving after this date will be held for the next year or returned on request.

HEART COMMITTEE MEETING

A SCIENTIFIC meeting of the Committee on Cardiac Clinics of the Heart Committee of the New York Tuberculosis and Health Association was held on February 28 at the New York Academy of Medicine. Papers read included one by Dr. Eugene M. Landis, and one by Dr. J. Murray Steele, and discussions by Dr. J. Hamilton Crawford and Dr. Alfred E. Cohn.

NATIONAL BOYS' WEEK

A MANUAL of suggestions for the preparation of a complete program for each day of Boys' Week—April 29 to May 6—is in preparation. The Committee will be glad to mail, gratis, copies of this manual directly to any unit of your organization which requests them.—National Boys' Week Committee, 211 West Wacker Drive, Chicago, Ill.

A.N.A. DELEGATES TO CONGRESS

THE official delegates from the American Nurses' Association to the Congress of the International Council of Nurses in Paris and Brussels next July were named at the January board meetings. They are Elnora E. Thomson, Susan C. Francis, Adda Eldredge and Katharine Tucker. Some 25 persons from the United States are on the program either for papers or for discussions. Miss Thomson, Miss Geister, Miss Roberts, and Miss Eldredge are among those invited to read papers.

OHIO STATE HEALTH DEPARTMENT

REORGANIZATION of the Ohio State Health Department into 6 divisions instead of 9 was announced

in December, 1932, by Dr. Harry G. Southard, Ohio State Health Officer, Member A.P.H.A. Dr. Emery R. Hayhurst, of Columbus, F.A.P.H.A., formerly consultant in the division of industrial hygiene, has been appointed chief of that division. Dr. Elgie R. Shaffer, F.A.P.H.A., was appointed chief of the child hygiene division. Dr. Reaves W. DeCrow, of Portsmouth, member A.P.H.A., succeeds Dr. Shaffer as head of the bureau of local health organization.

PERSONALS

MARY AUGUSTA CLARK, F.A.P.H.A., is now Research Associate in the Division on Community Clinics of the National Committee for Mental Hygiene. In this position, Miss Clark is continuing a consultant service with reference to statistical records and reports in child guidance and adult psychiatric clinics which she has given for the past 7 years as a member of the Commonwealth Fund.

JANET M. GEISTER, R.N., director at headquarters of the American Nurses' Association, resigned January 30, the resignation to go into effect March 15. Mrs. Alma Scott, the associate director, will carry on the director's duties for the present.

MRS. MARIE F. KIRWAN, of the State Charities Aid Association of New York, is now chairman of the Department of Public Welfare, New York State Federation of Women's Clubs. This includes all forms of health activities covered by the clubs.

DR. FRANK JOSEPH JIRKA, of Chicago, was appointed Illinois State Health Director on January 25. During the 40 years of its existence, 5 different physicians filled the office of chief executive for one full term or more. Dr. Jirka succeeds Dr. Andy Hall, of Springfield, member A.P.H.A., who resigned.

DEATHS

CHARLES BUCKLEY MAITS, M.D., F.A.P.H.A., Director of the Department of Public Health of Pittsburgh, Pa., died early in January. Dr. Maits was active in the Air Pollution Investigation, which has been carried on for years by the Mellon Institute of Industrial Research.

DR. H. K. READ, F.A.P.H.A., of Houston, Tex., died in December, 1932. He was the supervisor of hygienics for the Houston public schools for the last six years.

CONFERENCES

March 21-25, Fourth Pan-American Medical Congress, Dallas, Tex.

April, American Physiological Society, Cincinnati, Ohio.

April 3-8, New York Food and Health Exposition, Grand Central Palace, New York, N. Y.

April 4-6, American Water Works Association, Southeastern Section, Albany, Ga.

April 29-May 6, National Boys' Week.
May 29-31, Western Branch, A.P.H.A., Pasadena, Calif.

June, State and Provincial Health Authorities of North America, Washington, D. C.

June, State and Territorial Health Officers Conference, Washington, D. C.

June 11-17, National Conference of Social Work, Detroit, Mich.

June 12-17, American Medical Association, Milwaukee, Wis.

June 26-30, National Tuberculosis Association, Toronto, Canada.

June 26-30, Annual Meeting of the American Home Economics Association, Milwaukee, Wis.

June 27-July 1, Convention of the Association for Childhood Education, Denver, Colo.

July 1-7, National Education Association, Chicago.

July 5-9, International Union of the Protection of Childhood, Paris.

July 10-15, International Council of Nurses, Paris, July 10-12; Brussels, July 13-15.

July 18-20, International Congress of Pediatrics, London.

July 25-29, British Medical Association, Dublin.

July 29-August 4, World Federation of Education Associations, Dublin.

MEDICAL BUREAU

The Medical Bureau has available class A physicians, dentists, graduate nurses and laboratory workers who have specialized in public health work. All credentials have been thoroughly investigated. Those in need of such personnel may receive complete biographies including statements regarding candidates' ability, integrity, and responsibility. No charge to employers for the introduction of applicants. M. Burneice Larson, Director, The Medical Bureau, Pittsfield Building, Chicago.

Recognition and Control of Tuberculosis of Childhood*

EUGENE L. OPIE, M.D.

*Department of Pathology, Cornell University Medical College,
New York, N. Y.*

MUCH progress has been made during the last decade in the recognition of pulmonary tuberculosis of both children and adults. We know more about the potential significance of the lesions that are recognizable, and this knowledge I have no doubt can be used to facilitate its control if applied primarily to children known to be living in contact with the disease. Furthermore, tuberculosis may be added to the list of diseases that may be effectively combated in school children.

This increase of knowledge has come from a variety of sources in part apparently far removed from practical uses. We have long admitted the approximate truth of the statement that everybody has a little bit of tuberculosis. A few years ago the occurrence of tuberculous lesions in the bodies of those who had died from other diseases was regarded as an interesting pathological observation of scant practical significance. Evidence collected very recently has shown that tuberculous lesions of children and adults who are

apparently in good health show wide variation in extent and severity. Roentgenological examination and tuberculin tests often reveal in the chests of apparently healthy persons extensive tuberculous lesions that though latent are progressive and ultimately develop clinically manifest disease, with its well known symptoms and physical signs. The early diagnosis and cure of tuberculosis is in considerable degree contingent upon the recognition of pulmonary disease before it has undermined health.

Widespread recognition of the significance of the tuberculin reaction and demonstration that roentgenological examination of the chest reveals both healed lesions and potential disease profoundly alters our conception of the epidemiology of tuberculosis. The tuberculin reaction discloses existing tuberculous infection, and roentgenological examination within certain technical limitations measures its anatomical extent. Consideration of the occurrence and spread of tuberculosis formerly included only those who were actually suffering with the disease. Now it is possible to determine the incidence of tuberculous infection that has not

* Prepared for the Public Health Nursing Session of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

impaired health, to measure its severity, to separate with a fair degree of accuracy healing and potentially progressive infection, and to follow the gradual transition of the latter into manifest disease.

Two varieties of investigation have been notably successful:

1. Study of the spread of tuberculous infection in families in which some member suffers with the disease. This form of investigation has for the first time disclosed the progressive development of latent tuberculous lesions in those exposed to the contagion, and has shown how frequently in contact children these occult lesions pass over into clinically manifest disease. It has given an insight into the spread of the disease among those exposed to it heretofore not obtainable.

2. Study of the occurrence of tuberculosis in school children offers the opportunity to determine the incidence of infection in otherwise unselected groups of children between ages 5 and 18 years. It has again shown the frequency of advanced tuberculous infection in those who are apparently well, and has disclosed furthermore a significant number of children who are suffering with clinically manifest tuberculosis that has not attracted the attention of their parents, teachers or physicians. It has shown that tuberculosis can be added to the list of diseases that may be profitably combated in public and other schools, and has further demonstrated that open air schools, summer camps, and preventoria can accomplish very little in the control of tuberculosis until attention of those concerned with their conduct is focused upon the technical medical problem involved in the discovery and prophylactic care of the disease.

The procedures outlined have been used with varying success in a number of places in this country with the double purpose of applying methods adapted

to early recognition of the disease, and of obtaining new information concerning its prevalence and mode of spread. In some instances it is not fully realized that recognition of tuberculosis is dependent upon technical methods that require considerable training and experience, and that the interpretation of the results obtained demand an intimate knowledge of the pathology, pathogenesis, and clinical course. To speed the progress of this work, it is highly desirable that observations be made in different places by comparable methods and that the lesions under consideration be described and classified, though perhaps differently, in such terms that one observer may understand another.

HOUSEHOLD CONTACT WITH TUBERCULOSIS

Studies made at the Henry Phipps Institute (Opie and McPhedran) have shown how tuberculosis, recognized before it produces symptoms, and as clinically manifest disease as well, spreads through households exposed to a person suffering with it. The fate of exposed children varies with age. A large part of the infants who are infected and become sensitive to tuberculin die from the disease. Young children are promptly infected, and during the first five years of life, more than 80 per cent exposed to tuberculosis in their homes react to tuberculin. Nevertheless, in the period between 5 and 15 years tuberculosis in the children of these families tends to pursue a benign course. At this time of life, calcified nodules of healing tuberculosis make their appearance in the lungs and adjacent lymph nodes in increasing number as age advances and are demonstrable in roentgenographs. Unfortunately at an earlier stage in their development when the same lesions are caseous, uncalcified and still progressive they are in most instances too small to make any impression upon the X-ray

film. A few, however, are so extensive that they cast a recognizable shadow and are obviously referable to tuberculous infiltration of the lung parenchyma. Such lesions of childhood type may remain latent, but in about one-fourth of all instances, develop symptoms and physical signs and tend to impair health and diminish weight. These children suffer with clinically recognizable pulmonary tuberculosis in the usual sense. Nevertheless it is now widely recognized that in a large part of children between infancy and adolescence infiltrative lesions of tuberculosis tend to pursue a favorable course. Infiltration of considerable extent tends to disappear and soft flocculent or even dense homogeneous shadows may be transformed into the strand-like picture of a fibrous scar. After 10 years of age these pulmonary lesions of childhood type seldom make their appearance in white children. When children living in contact with tuberculosis reach adolescence, latent pulmonary lesions of adult type begin to develop somewhat earlier in girls than in boys, and their frequency increases in the later years of this period of life. These apical lesions pursue a much more unfavorable course than those of the childhood type. In the adolescent and young adult members of exposed families, such lesions often become manifest, causing cough, loss of weight, and physical signs, and with further progress of the disease, tubercle bacilli may be found in the sputum.

EXOGENOUS REINFECTION WITH TUBERCULOSIS

The evidence indicates that the lesions of adult type appearing in adolescence are the result of new infection and almost invariably result from continued contact with a person who suffers from the adult type of pulmonary tuberculosis, and disseminates tubercle bacilli present in the sputum.

Apical tuberculosis becomes evident at a time when lesions of first infection are demonstrable as calcified or fibrous scars and are evidently healed or healing. Anatomical and experimental evidence gives abundant support to the opinion that the adult type of tuberculosis is, with few exceptions, the result of exogenous reinfection. Many even yet deny the possibility that adults can acquire tuberculous infection. This opinion is in great part based upon the statistical review of histories of husbands and wives exposed to the contagion of a partner with the disease. When roentgenographic examination was applied to the examination of persons exposed to marital contagion, convincing evidence that approximately half of them acquire apical lesions was obtained (Opie and McPhedran).

In what degree does first infection protect from reinfection? Evidently protection is ineffective since in adolescent children exposed to continued contact with the disease reinfection of adult type often ensues. Animal experiments indicate that with complete healing of a tuberculous lesion, sensitivity to products of the tubercle bacillus subsides and resistance to reinfection disappears. With continued exposure to tubercle bacilli or even with repeated casual contacts with the microorganism, such as evidently occur in children not exposed to household infection, sensitivity and presumably resistance is maintained. Nevertheless long continued exposure to the immediate environment of a person who is expelling tubercle bacilli may overcome this resistance.

EXTRA-FAMILIAL INFECTION WITH TUBERCULOSIS

The preceding discussion has shown that familial contact with open tuberculosis almost invariably results in infection, often with the production of extensive lesions and manifest disease.

Tuberculin tests and radiographic examination of children who are not exposed to family contact with the disease reveal tuberculous infection with increasing frequency as age advances, but the incidence is far less than in children with known exposure. Of children in household contact with open tuberculosis, 80 per cent have acquired infection in the period between infancy and 5 years, whereas in children not exposed to family contagion, this incidence of infection is not reached until the age of approximately 17 years (Opie and McPhedran). Radiological examinations show that the lesions of children not obviously exposed to contagion are with few exceptions of scant severity and are recognizable as calcified healed or healing nodules of lungs or lymph nodes. It must be assumed that these infections, almost universal in large cities, are the result of casual contact with the microörganism, but it is not possible to define exactly the conditions under which they occur.

Aronson has shown that intensity of the tuberculin reaction tends to increase with age, so that reactions revealed only when 0.1 or 1 mg. of old tuberculin is used are more frequent in the period from birth to 20 years of age, whereas reactions to 0.01 mg. are more frequent after this age. It is probable that children who are acquiring infection for the first time, usually as the result of casual contact with the disease, pass through a period in which there is scant sensitivity to tuberculin. In view of the increasing frequency with which infection is found by means of the tuberculin test between infancy and early adult life, it is evident that children are constantly coming into contact with tubercle bacilli during this period. Somewhat later in early adult life repeated impact with the micro-organism doubtless continues, since the incidence of the reaction during the age period from 25 to 50 years approximates

100 per cent. The reaction to tuberculin disappears with complete recovery from infection, but sensitivity of adults is in general maintained with greater intensity than that of children. After 70 years of age there is a slight diminution in the incidence of the reaction, perhaps due to diminishing exposure of very old persons to infection.

The evidence available indicates that the childhood type of pulmonary tuberculosis even within the household is an insignificant source of contagion. The usual benign course of this form of the disease, infrequently accompanied by cavity formation, supports this opinion. The adult type of pulmonary tuberculosis which often pursues a chronic course with cavity formation and elimination of tubercle bacilli over a considerable period of years is the chief source of the dissemination of infection. The increase of grave tuberculous infection in adolescence and early adult life is best explained by increasing contact with adults suffering from open tuberculosis. The intimacy of contact in large part determines the severity of infection. The effects of marital contact are now clearly demonstrable. Why adolescent children, girls more frequently than boys, suffer infection is less evident, but might prove a fruitful field for investigation. Possible contagion, I believe, should receive first consideration.

CLASSIFICATION OF TUBERCULOUS LESIONS RECOGNIZABLE BY ROENT- GENOGRAPHIC EXAMINATION OF THE CHEST

It is certainly desirable that those who are engaged in the search for tuberculosis in school children and publish reports on the subject classify the lesions they find in such a way that the results of one are intelligible to others. It is, however, doubtful if a system of classification adopted by a committee or other conclave tends to

speed the accumulation of information.

The following classification of tuberculosis has been found useful in our studies of the epidemiology, clinical course, and pathogenesis of the disease conducted at the Henry Phipps Institute:

Latent Tuberculosis:

- A. Latent tuberculosis with hypersensitivity to tuberculin demonstrated by the intracutaneous test but with no lesions of the lungs demonstrable by roentgenographic examination.
- B. Calcified nodules in the lung.
- C. Latent infiltration of childhood type:
 - (a) Soft or flocculent (potentially progressive)
 - (b) Strand-like (healed)
- D. Tuberculosis of tracheobronchial lymph nodes:
 - (a) Calcified
 - (b) Massive caseous
- E. Latent apical tuberculosis (adult type of latent tuberculosis):
 - (a) Supraclavicular (see further subdivision)
 - (b) Supra- and infraclavicular (see further subdivision)
- F. Manifest pulmonary tuberculosis with sputum negative for tubercle bacilli:
 - (a) Childhood type
 - (b) Adult type
- G. Manifest pulmonary tuberculosis with tubercle bacilli in sputum:
 - (a) Childhood type
 - (b) Adult type
- H. Tuberculosis of organs other than the lungs
- I. Suspected tuberculosis

With this classification the stage of progress may be designated incipient, moderately advanced, or far advanced, and the present status of the disease suggested by the severity of its symptoms may be defined by such terms as quiescent, arrested, and apparently cured, in accordance with customary usage.

The word "latent" to designate tuberculosis unaccompanied by significant symptoms and physical signs is objectionable to some writers because they assume that it means arrested, obsolescent, or healed, but it is noteworthy that the present usage had had

the sanction of both Laennec and Louis who described as latent, phthisis not recognizable during life. In this sense, in accord with daily observation, latent tuberculosis revealed by the tuberculin test on the one hand may be so insignificant that it casts no shadow on a roentgenographic film, and on the other hand, occupying a considerable part of the lung parenchyma may menace health.

When routine roentgenographic examination is applied to groups of persons such as school children, college students, industrial or other workers, who are presumably well, a certain number are found to have conspicuous infiltrating lesions of the lung accompanied by physical signs, such as râles, impaired resonance, or diminished breath sounds. Questions may now reveal some cough or loss of weight that had previously attracted little attention. Although these persons have clinically manifest tuberculosis they form a group not included among those who apply to a physician because they have "come down" with symptoms of tuberculosis. They are found only when X-ray examination is applied to those who are assumed to be well.

DEVELOPMENT OF MANIFEST PULMONARY TUBERCULOSIS FROM LATENT TUBERCULOUS INFECTION

Observations made by McPhedran and the writer in process of publication define the frequency with which different kinds of latent tuberculous lesions become clinically manifest disease. These observations were made upon children attending the dispensary of the Henry Phipps Institute during a period of 8 years, and in different cases the length of observation within this limit has varied widely.

Table I shows the frequency with which latent lesions of childhood type found in children below the age of 15 years become manifest.

Infiltration of the lung of childhood type represented by diffuse opacity or mottling of the roentgenographic film has developed clinically manifest disease in about one-fourth of the instances observed. In these cases pulmonary tuberculosis usually pursues a benign course. Strand-like infiltration with few if any exceptions is a healed lesion and has no more significance than a calcified nodule found in the lung parenchyma.

Massive caseous tuberculosis is a dangerous lesion and in nearly half of the cases observed was ultimately associated with clinical disease.

There is small probability that calcified nodules found in the tracheo-bronchial lymph nodes will give rise to clinical disease. With them the incidence of manifest tuberculosis has been less than 2 per cent, and in many cases the child has remained in contact with the source of infection.

Table II shows the frequency with which latent lesions of adult type have become manifest. Since the fate of lesions varies with their extent, it has

TABLE I

SHOWING FREQUENCY WITH WHICH LATENT LESIONS OF FIRST INFECTION (CHILDHOOD TYPE) IN CHILDREN (0-15 YEARS) DEVELOP CLINICALLY MANIFEST TUBERCULOSIS

| <i>Latent lesion</i> | <i>Number of children</i> | <i>Number that developed clinically manifest tuberculosis</i> | <i>Per cent that developed clinically manifest tuberculosis</i> |
|---|---------------------------|---|---|
| Soft infiltration of lung | 38 | 9 | 23.7 |
| Strand-like infiltration of lung | 6 | 0 | 0.0 |
| Massive caseous tuberculosis of tracheo-bronchial lymph nodes | 11 | 5 | 45.5 |
| Calcified tuberculosis of tracheo-bronchial lymph nodes | 163 | 3 | 1.8 |

TABLE II

SHOWING THE FREQUENCY WITH WHICH WHITE CHILDREN (10 TO 20 YEARS) WITH LATENT APICAL TUBERCULOSIS HAVE DEVELOPED CLINICALLY MANIFEST TUBERCULOSIS

| <i>Extent of lesion</i> | <i>Number with latent apical tuberculosis</i> | <i>Number that developed manifest tuberculosis</i> | <i>Per cent that developed manifest tuberculosis</i> |
|---|---|--|--|
| Group 1 Scant lesions | 10 | 2 | 20.0 |
| Group 2 Approximately half of apex above clavicle | 15 | 5 | 33.3 |
| Group 3 Equivalent to minimal tuberculosis | 12 | 7 | 58.3 |
| Group 4 Equivalent to moderately advanced tuberculosis | 3 | 2 | 66.6 |

been necessary to separate them into groups. The first group contains scant but definite lesions evident in the film as opaque spots or salients projecting below the margin of the second rib. Group 2 contains lesions occupying approximately half or more of the apex above the clavicle. Groups 3 and 4 contain lesions which extend below the clavicle. In group 3 are lesions equivalent in extent to those of minimal pulmonary tuberculosis, and in group 4 those equivalent to moderately advanced disease.

The table shows that the extent of latent lesions is an index of their danger, the incidence of subsequent manifest disease varying in the different groups from one-fifth to considerably over one-half of the small number of cases observed. Repeated roentgenological examination of these latent lesions is essential in order to determine if they are progressive. It is noteworthy that latent apical lesions

pursue a much more unfavorable course than similar lesions of childhood type.

THE TUBERCULIN REACTION

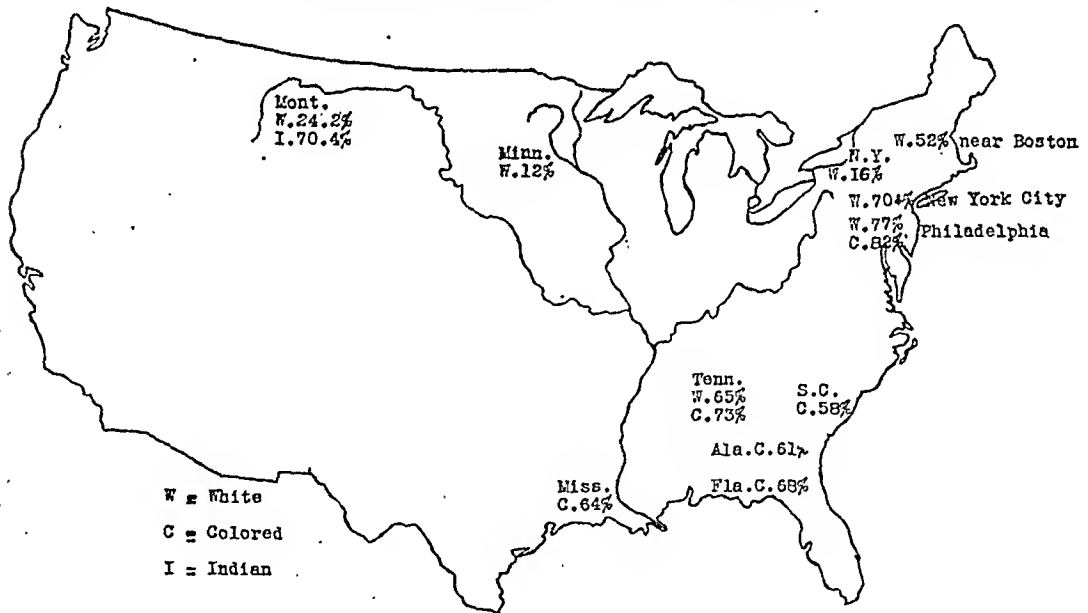

Since the tuberculin reaction is being used with increasing frequency to determine the incidence of tuberculous infection, it may be useful to consider what can be learned from it and the limitations of its usefulness. The method of application is important since exact results are obtainable only by the intracutaneous method with introduction of accurately measured quantities of tuberculin into the dermis.

Tuberculin varies so widely in strength that it is essential to standardize the sample in use by tests on animals. "Old tuberculin" is more

diminishes rapidly with increasing age. Nassau and Sweig found that of 20 children with tuberculin reactions which had appeared during the first 3 months of life, all died; of 16 infected during the second 3 months, 87.5 per cent died; but of 13 infected during the second half of the first year, only 30.8 per cent died. Asserson points out that infants subjected to continuous exposure in their homes have only a slight chance of escaping disease and death from tuberculosis, whereas those who receive their infection more casually and less continuously exhibit much greater resistance.

With increasing age the tuberculin reaction occurs so frequently that it cannot be used to identify children who

FIGURE I—OBSERVATIONS SHOWING PERCENTAGE OF TUBERCULIN REACTIONS AT THE AGE OF 15 YEARS IN SOME PLACES IN THE UNITED STATES

trustworthy than recently introduced preparations the effects of which are as yet uncertain.

In an infant living in contact with tuberculosis a tuberculin reaction recognized in the first few months of life indicates the existence of a grave tuberculous infection from which death will probably result. The prognostic significance of a reaction to tuberculin

will develop clinically manifest tuberculosis. A negative tuberculin reaction however with few exceptions demonstrates the absence of tuberculous infection and renders examination by X-ray unnecessary. Nevertheless grave latent lesions are found with greatest frequency in children with intense tuberculin reactions (Opie and McPhedran). The reaction tends to

diminish somewhat in intensity with the appearance of symptoms and physical signs.

The incidence of the tuberculin reaction in school children in different parts of the United States varies within astonishingly wide limits (Figure I). The percentage of those who react at the age of 15 years may be used as an index of the frequency with which infection has been acquired during earlier childhood. A curve plotted in 5-year periods may be used to estimate this figure. In the larger cities the incidence of the reaction is high. In Philadelphia 77 per cent of white children in public schools and 83 per cent of colored children react to tuberculin (Hetherington, McPhedran, Landis and Opie). In New York 70.4 per cent of children aged 14 years reacted (Barnard, Amberson and Loew); in a suburban district near Boston approximately 52 per cent of children at the age of 15 years reacted (Aronson and Zaks). In certain rural districts in several northern states few children are infected in early childhood. Slater in rural districts of Minnesota found that only 12 per cent of children at the age of 15 years reacted to tuberculin; and Korns in Cattaraugus County of New York found that 16 per cent reacted. In rural districts of southern states (Tennessee, Alabama, Florida and Mississippi), Aronson found a much higher incidence varying from 60 to 70 per cent and wherever comparison was possible, obtained a uniformly higher percentage in negro than in white children. Significant observations have been made by Crouch in Montana. Here only 24.2 per cent of white children reacted to tuberculin at the age of 15 years, whereas of full blood Indian children of the same age, approximately 70.4 per cent reacted.

The figures suggest many questions that can best be answered by further observations similar to those cited. All

we know about immunity against tuberculosis indicates that infection confers some, but limited, resistance to the disease. We have very little direct information about the fate of those who are exposed for the first time during adolescence or early adult life to infection. Anatomical observations demonstrate that such first infection often pursues a rapidly fatal course.

SPUTUM EXAMINATION

The commonplace procedure of sputum examination for tubercle bacilli is widely neglected as a public health procedure for the discovery of those who are disseminating the disease. Lack of the meager laboratory facilities required to make numerous sputum examinations or the inaccessibility of laboratory facilities, especially in rural communities, is sometimes responsible for this neglect. The physician who suspects diphtheria recognizes the urgent need of bacteriological examination but is not infrequently apathetic concerning the search for tubercle bacilli when tuberculosis is suspected.

Experience at the Henry Phipps Institute during the last 8 years has shown that children and adults in families of which some member suffers or has suffered from tuberculosis with sputum containing tubercle bacilli are almost invariably infected, latent lesions are advanced, and manifest disease frequent, whereas in families of which a member has tuberculosis with sputum negative, by the usual method of examination, tuberculous infections are often little more frequent or severe than in families with no contact with tuberculosis, and manifest tuberculosis seldom makes its appearance. From the standpoint of public health the separation of pulmonary tuberculosis disseminating tubercle bacilli and that with no tubercle bacilli in the sputum is essential.

Municipal registration of tuberculosis,

grossly imperfect as it is, and the experience of dispensaries such as that of the Henry Phipps Institute demonstrate very clearly that a large part of those with open tuberculosis still remain in their homes and die in contact with their families, infecting a new generation by years of exposure to contagion. We are in considerable part consoled by the thought that the death rate from the disease, still enormous, is less than formerly.

From the standpoint of the patient, frequently repeated sputum examination has much value, for if tubercle bacilli are present in the sputum there is imminent danger of pulmonary dissemination by way of the bronchi. Disappearance of tubercle bacilli from the sputum is significant evidence of improvement. Patients visiting a physician or attending a dispensary should be instructed concerning the value to themselves of sputum examination. They should realize that their physician can better measure the progress of their disease if they bring a specimen of sputum when obtainable at each visit. When sputum is obtainable it should be examined for tubercle bacilli at least once every month. Sputum examination is an index of the danger to which the patient and those about him are exposed.

CARE OF SCHOOL CHILDREN WITH ADVANCED TUBERCULOUS INFECTION OF THE LUNGS

The information recently accumulated concerning the occurrence of grave latent lesions and manifest tuberculosis in school children is obviously applicable to the control of the disease. The children who are known to be living in contact with persons disseminating tubercle bacilli are in greatest danger. Since it has proved impossible to discover and register a large part of those who suffer with open tuberculosis, contact of school children

with the disease will often escape detection. Nevertheless, were it feasible for municipal bureaus for registration of tuberculosis to coöperate with the medical inspection of school children many pupils living in contact with the disease could be brought under observation and prophylactic care.

Routine examination of school children by physicians adequately trained to employ available technical methods will reveal a large part of those who suffer with early manifest disease or progressive latent infection. This is expensive, and the interpretation of X-ray films to be effective requires intimate knowledge of the clinical course and pathogenesis of tuberculosis. Hence in the present state of our knowledge of the subject it should be employed with the double purpose of discovering children with grave infection and of obtaining new information that will aid in retarding the progress of discoverable infection. Ability to recognize potential disease has been greatly increased, but as yet no material progress has been made in developing those administrative procedures which are needed to put school children with obvious tuberculosis under conditions favorable to their recovery.

Four groups of children come under consideration:

I. *Children with latent tuberculous infection indicated by tuberculin reaction alone or tuberculin reaction in association with roentgenographically demonstrable lesions that experience has shown are healed or healing, and will not develop into clinically manifest tuberculosis*—This group with lesions already defined includes a considerable part of all school children. Their infection does not threaten their health.

II. *Children with demonstrable latent infection of the parenchyma of the lung*—I have attempted to define our knowledge of the potential significance of the various pulmonary lesions that

are recognizable by roentgenographic methods, but this knowledge is still inadequate and further experience extended throughout the childhood and early adult life of many children is needed. Children with these advanced latent lesions should receive such care as will insure them against further progress of their infection. Machinery for the care of these cases, mainly open air schools, summer camps and preventoria* are available and are receiving considerable support, but their medical administration with few exceptions is wholly inadequate for the prophylactic control of tuberculous infection. Whenever latent infiltrating lesions of the lung are recognizable, repeated X-ray examination to determine if the infection is progressive becomes an essential part of any effort to check the infection.

III. *School children presumably well enough to attend school who by routine roentgenographic and physical examination are found to have clinically manifest tuberculosis*—In these children grave tuberculous lesions of the lungs are discovered by roentgenographic examination, and subsequent questioning or physical examination reveals symptoms or physical signs of tuberculosis. They are often well nourished and usually show no diminution of

weight (Hetherington). No grave impairment of health is suspected by parents, teachers, or medical inspector of the school. Unfortunately it is often difficult to convince the family physician that the child has pulmonary tuberculosis. When cough or significant physical signs accompany roentgenographic evidence of pulmonary tuberculosis, the need of sanatorium care or its equivalent is obvious.

IV. *Children whose health has been conspicuously impaired by pulmonary tuberculosis*—Children who are brought by their parents to a physician or referred by their teacher to the school medical inspector because they suffer with cough, loss of weight, fever, or other symptoms found to be referable to tuberculous lesions of the lung, have in popular phrase "come down" with the disease. In such cases pulmonary tuberculosis is usually well advanced and a grave menace to life.

It is the usual practice of physicians specially concerned with the treatment of tuberculosis to recommend sanatorium care or its equivalent to patients with clinically manifest tuberculosis, even though the disease is regarded as incipient. The evidence that has been reviewed in this paper demonstrates I believe that children in whom progressive latent infection of the lung substance is demonstrable by repeated roentgenological examination should be treated as though they had manifest disease and receive the same care. The small number of children with massive caseous tuberculosis of tracheobronchial lymph nodes should be included in the same group.

Observations made in Philadelphia, obviously applicable with exactness only to the children who were examined, showed that latent infiltrating pulmonary lesions of childhood type occurred in 1.2 per cent of children between the ages of 5 and 9 years (inclu-

* An open air school was first established at Charlottenburg near Berlin in 1904. It may be assumed that access to fresh air has been regarded as a symbol for all the agencies that are adapted to promote child health and control the progress of an infection such as tuberculosis. The establishment of these schools and school classes has been widespread. In 1926 the Elizabeth McCormick Memorial Fund had recorded 1,036 open air schools for 32,064 pupils distributed among 245 cities of this country. The figures are now doubtless considerably larger.

Preventoria which provide continuous maintenance have, as the name implies, a similar though often ill defined aim. Records of the National Tuberculosis Association in 1930 showed that there were in this country 32 preventoria with accommodations for 1,600 children and 57 preventorium units attached to sanatoria for 3,400 children. The number up to 2 years ago at least was increasing rapidly, and financial support for institutions of this kind was evidently available.

sive), 1 per cent in those from 10 to 14 years, and 0.2 per cent in those from 15 to 19 years. These lesions occur in great part in children of the elementary schools. They usually pursue a benign course but are not negligible. Open air classes with a régime adapted to insure adequate nourishment and freedom from mental and bodily fatigue give promise of controlling these lesions, provided that medical service and technical facilities are available to determine as accurately as possible the progress of tuberculous infection.

Among high school children the apical lesions that are recognizable tend to pursue a less favorable course (see Table II). In Philadelphia latent pulmonary tuberculosis of adult type was found in 0.5 per cent of children between 10 and 14 years of age, and in 1 per cent of children between the ages of 15 and 19 years.

The school régime adapted to protect pupils of the elementary school from further progress of grave latent tuberculosis is evidently not equally applicable to the older children who attend high schools. Their assignment to classes with specially arranged schedules presents many difficulties. Nevertheless should their progress in the school be subordinated to the immanent demands of their health, it is possible to diminish their hours of work by limiting the number of their courses, to provide periods of rest, to avoid fatigue, and to insure adequate nutrition. Continuous medical supervision and periodic physical and roentgenological examination are of primary importance. When medical examination demonstrates clinically manifest disease, or roentgenographs disclose progress of the lesion, the child should be withdrawn from school and

receive sanatorium treatment or what is regarded as the equivalent of that.

The adequate care of high school pupils with latent tuberculous lesions of the lung presents many difficulties to the school administration. Since the health of these pupils is not obviously undermined, pupils, parents, and not infrequently their family physician, may be earnestly opposed to measures that will retard the child's progress in the school. The administrative officers of the school and other teachers find many difficulties in modifying the number and arrangement of courses to meet the needs of pupils with potential disability. The care of these adolescent children moreover requires space and facilities for rest often not readily available. Furthermore latent tuberculosis of adult type is discovered during the period of adolescence and beginning adult life with increasing frequency as age advances, and is often first recognizable when the pupil is approaching the end of the high school course. In such instances school medical inspection will have accomplished the important function of recognizing potential disease but subsequent care must be assigned to other agencies.

CONCLUSIONS

With the aid of adequate technical facilities, grave tuberculous infection can be recognized in a small percentage, constituting a very large number, of school children. The severity of the lesions that can be found in children whose health is not obviously impaired demonstrates the need of medical care directed to control the further progress of infection. Medical care will be ineffective unless it is coördinated with a school régime adapted to the same end.

Tuberculosis of Bovine Origin*

MAZYCK P. RAVENEL, M.D., F.A.P.H.A. (*Life Member*)

University of Missouri, Columbia, Mo.

SOME 10 years ago I took occasion to point out the injury which had arisen to this Association through specialism. The reference at that time was chiefly to membership, since many special societies have arisen which duplicate the work done in our sections, and it is but natural that specialists should seek membership in the particular societies devoted to their branch.

I now wish to point out another injury which has arisen from the same cause. One finds in the transactions of our earlier meetings many papers on tuberculosis, but for some years, very few have been written on this subject for our Association. It is true that we have dealt extensively and repeatedly with milk, and have a standing committee for the study of this food product. It is true that we have had a number of discussions on pasteurization, and to a certain extent tuberculosis has been considered in these various reports. Recent studies in this country, England, and Canada, have forced me to the conclusion that we have not been sufficiently active in regard to tuberculosis and that it is time for this Association to take up the matter more actively, especially as regards the transmission of bovine tuberculosis to human beings. I may point out that while the death rate from tuberculosis for 1931 was 57 per 100,000, just a third of what it was for

1904, tuberculosis still leads as a cause of death during the prime of life—from 15 to 45 years of age—and shows a marked increase in young unmarried women, the cause of which is not entirely evident.

The subject of bovine tuberculosis was a matter of hot discussion for some years following Koch's address before the London Congress on Tuberculosis in 1901, but for some years little has been heard concerning it, except from our Bureau of Animal Industry, to the officers of which all praise must be given for their splendid work.

In April, 1932, we had the report of a committee of 60 appointed by the Peoples' League of Health in England,¹ a league which was set in motion by Olga Nethersole, the great actress. It showed that 40 per cent of the cows in Great Britain are infected with tuberculosis, while 6.7 per cent of the samples of market milk from various parts of the country contained living bovine tubercle bacilli, and further, that 2,000 deaths occurred annually from this cause, largely in children, while 4,000 new cases of the disease developed, and pointed out that since glandular tuberculosis was not reported, this latter figure was considerably below the facts. During the same month the report of the Committee on Prevention and Research of the International Society for Crippled Children² stated that tuberculosis stood second only to infantile paralysis as a crippling disease, that from 10 to 15 per cent of the cases of bone and joint tuberculosis are of bovine origin, and that of children

* Presented at the Ten Star Final Special Session of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

suffering from tuberculosis from 0 to 5 years of age, 21 per cent, and of those 5 to 16 years, 26 per cent derived their infection from the bovine germ. At the University of Toronto, Dr. R. M. Price^{3, 4} has been typing cultures from cases of tuberculosis, and has found that of 340 patients studied, 13 per cent were infected from bovine sources. This work afforded a most striking demonstration of the value of pasteurization, since in Toronto, where the milk supply is pasteurized, not a single case of bovine infection was found, while in the Province of Ontario the figures just stated prevailed.

What do the figures presented mean to us in the United States? It is freely confessed that we have no grounds for an estimate even approximately correct, but if the British figures of 1 death for every 2 cases—which is manifestly short of the truth—holds, it indicates a death rate from bovine tuberculosis for which we should blush, and to prevent which every effort should be made. I have elsewhere given an estimate of 3,500 to 4,000 deaths, based on the annual death rate for 5 years of 7,000 children, but further study has convinced me that my figures were too high. Of the cases of bone and joint tuberculosis, 6 per cent are fatal.

So much for the facts. Along what lines can our Association show activity with benefit? The matter of the eradication of bovine tuberculosis is being competently handled by our Bureau of Animal Industry, and the reduction in the disease passes what most of us believed possible only a very few years ago. This part of the work can well be left to this agency and to the veterinary profession, though we should recognize their work and aid it whenever and wherever possible. We are much better off in respect to infected cattle than are the English. The percentage of infected cattle in this country is estimated at 1.9, and of tuberculosis

of the udder at 0.1, but among dairy herds, the figures run higher, though I have been unable to obtain the exact percentage from the Bureau of Animal Industry. Pasteurization of milk, which was formerly urged largely on account of the danger of bovine tuberculosis, is being pushed by our Association and by competent health officers throughout the country for other reasons also, so that practically all of our large cities have a safe milk supply through this process. This work must be continued until pasteurization is the rule in small cities and towns, as there is some reason to believe that tuberculosis is on the increase in rural districts.

Directly connected with the prevention of tuberculosis is the matter of nutrition. It is universally conceded that milk is an essential food for infants and children, and the best results shown in the fight against tuberculosis came when the consumption of milk was greatest. Since 1929, the amount of milk consumed has been decreasing. One estimate places this decrease at 20 per cent. The two products, the use of which show the greatest falling off, are whole milk and ice cream. Here is a field in which every member of our Association, whatever his special line, can take a part by teaching that portion of the public with whom he comes in contact the benefits of milk as a food and the necessity of its use for growing children.

While our Association does not go into treatment of disease, we recognize that every case of contagious disease which is well cared for wipes out a focus of infection. For tuberculosis, more than for any other single disease, early diagnosis and the prompt institution of treatment are most important for recovery as well as prevention. A recent survey of our medical colleges shows that only 19, or 29.7 per cent, have special departments for teaching tuber-

culosis; 9, or 14.1 per cent, divide the work between a specialist and the internist; while 33, or 51.6 per cent, have specialists for teaching without distinct departments for the work. Our Committee on Training and Personnel might well, it seems to me, lay stress on the study of tuberculosis. Our public nurses have many opportunities for putting such knowledge into effect, and every health officer comes up against the problem almost daily.

Note: Since the above was written, the *Special Report Series No. 172* of the English Medical Research Council has appeared and

been reviewed in the *London Lancet* for October 15, 1932.

From 1,800 consecutive autopsies at the Glasgow Royal Hospital from 1924 to 1931, in which the type of tubercle bacilli isolated at autopsy, both from those dead of tuberculosis, as well as from other causes, and cases of surgical tuberculosis still alive, Dr. Blacklock concludes that 37 per cent of the bacilli were of the bovine strain. This makes him think that bovine tuberculosis is even more common in Scotland than in England, or on the continent.

Activities and Trends in the Laboratory Field*

GEORGE W. MCCOY, M.D., F.A.P.H.A.

*Director, National Institute of Health, U. S. Public Health Service,
Washington, D. C.*

THE invitation to attempt an interpretation of the activities and trends in research work on behalf of the Laboratory Section was accepted with some reluctance. This reluctance sprang chiefly from a feeling of perplexity as to what might be presented to you, and I beg of you to note that the subject is not "Advances and Achievements in the laboratory field." Perhaps it always has been so, but just now seems to be a time of more than ordinary questioning of old views and of what were thought to be well established facts. Indeed, some of the more progressive workers in the field of bacteriology are subscribing to a new creed in which "I believe"

becomes "I do not believe." To these the postulates of Koch, long regarded as the very foundation of all that we regarded as well established, become of no more significance than an outworn slogan of the last political campaign.

I am prompted to listen, at least sympathetically, and perhaps respectfully, to the apostles of the newer faith by the recollection of the fact that advocates of the revolutionary always travel a hard road—witness especially Semmelweiss. For the benefit of those who may not be especially interested in medical history, I should like to say that Semmelweiss was a Vienna physician who was much disturbed by the maternity mortality in a great lying-in hospital. He had one of the earliest conceptions of what we would now call an "epidemiological study," and on the

* Presented at the Ten Star Final Special Session of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

basis of his observations he made a suggestion that led to his scientific crucifixion—and what was the suggestion that had this disastrous personal result? It was only that medical attendants of parturient women should not go practically directly from the performance of an autopsy to attending at a childbirth.

I have a feeling of suspicion that this progressive view may turn out to be more nearly right than many of us, perhaps the majority, are willing to concede. I make no pretense to be in a position to express any opinion on the merits of these new contentions and perhaps my suspicions that they will prove sound arises from a recognition of the fact that, so far as concerns this country, like prohibition and woman suffrage, they have come out of the West. Some of the progressives modestly offer a new interpretation of certain observed facts regarding them as stages in vital histories of readily visible forms—note how neatly I avoid the expression “life cycles,” and they see further in these life histories possible explanations of such mysteries as the why of the waxing and of the waning of epidemics.

Most of us are ready to accept variation among bacteria as applied to such readily demonstrated facts as colony types, and to acknowledge their great significance; but we are likely to have to go much beyond this. It is no fantastic possibility to see in some of the newer work an explanation of the hitherto mysterious rise of epidemics that have appeared to be spontaneous in their development. Such a view would require us to reconsider much that we have treasured in the shape of attributing outbreaks to “missed cases” and “carriers.” Instead, they may be looked upon as stages in the history of the infecting agent seeking to make for itself a place in the sun.

We have indeed traveled far—as one writer recently expressed it, “from the

static bacteriology of Lister and Ehrlich and Koch.” Medical bacteriology especially has been accused of being a millstone around the neck of the worker in fundamental bacteriological research. Possibly so, but let us console ourselves with the thought that even a millstone has a useful purpose to serve, though perhaps not when draped around the cervical region of a research worker. Perhaps the medical bacteriologist has centered his thought too closely on the practical application of the fruits of his investigations; but when one appraises the benefits that have come from this, much should be forgiven.

One of the outstanding facts that has impressed me in recent years has been the rich harvest to be garnered from the reworking of old fields. Let me illustrate: Up to perhaps a half dozen years ago we felt quite comfortable about our knowledge of yellow fever. I am sure that nearly everyone would have agreed that if there existed any one subject on which further work was not required, that was yellow fever. In spite of this, further work was undertaken, and on the basis of the more recent observations new methods of the transfer of the infection have been noted, new species of insect vectors proved, and an exact scientific method evolved for the recognition of those who are immune.

Another outstanding example is to be found in typhus. Here, too, we thought that our knowledge was rather complete though, as in yellow fever, we had not grown the causative organism. Certain outstanding differences in epidemiology between endemic typhus as observed in this country and epidemic typhus in other parts of the world, led to a search for new vectors and new reservoirs. This work has been successful in showing the rat to be a reservoir for the infection, and the flea to be a vector, and the evidence indicates that

out of the evil combination we have secured a knowledge of endemic foci and a suggestion to explain the prevalence of the disease in epidemic form.

Three years ago psittacosis was considered a rare disease of passing interest only. Following its rather spectacular spread over the world in 1929, we have learned that its etiological agent was not the organism that had hitherto been regarded as the cause. Infection of laboratory workers demonstrated the dangers involved in the study of the disease. New methods of study have to a large extent eliminated this risk. We have learned that probably we have been missing many cases, a point of importance to health officers and to physicians generally.

Relating to the phase of progress just described I want to mention the searching of our souls that is now going on, chiefly with respect to the exact usefulness of what have been regarded as established and tried agents and practices. The clinician points an accusing finger at the research worker and demands to know why antimeningococcus serum is disappointing him. He has been led to expect a death rate of somewhere in the neighborhood of 15 or 20 per cent, but in the extensive prevalence of meningitis of a few years ago in the West and Mid-west the death rate was nearer 50 per cent, and on the wrong side of 50 at that. If one goes to the trouble of studying the curve of meningitis fatality over a long period of years, he will find that it has been rising rather steadily for a couple of decades.

The last subject I mention under this head I approach with considerable hesitancy but, after all, what I have to say has been said before, so I suppose it is safe to remark that our sheet anchor, diphtheria antitoxin, is coming into the limelight for a new appraisal. It is no secret abroad that for the last 6 or 7 years parts of Europe have been having a type of diphtheria that is not

very amenable to antitoxin treatment. The time honored alibis of inadequate dosage and of delay in beginning the treatment do not appear to be so satisfactory as they have been in the past. There is nothing to indicate that a difference in immunological properties of either toxin or antitoxin accounts for the disappointing results, nor is there any other satisfactory explanation.

I might cite other examples in which the clinician has grievances growing out of his disappointments, but the two mentioned will suffice.

The public health administrative officer is rather pointedly inquiring as to why typhoid vaccine sometimes fails to prevent typhoid fever, and the same goes for rabies vaccine.

In this connection, I would like to point to Park's study of the clinical use of poliomyelitis convalescent serum in the treatment of that disease as a model of excellence. Without Park's work, which I think showed conclusively the want of value of the serum, we would have gone on for an indefinite time nourishing the delusion that convalescent serum was a valuable therapeutic agent in poliomyelitis.

Perhaps all of these examples demonstrate the necessity of epidemiological and of statistical work in support of laboratory findings.

We have had to concern ourselves too in recent years with essential complications of our prophylactic agents. The epidemiological and the laboratory investigations of tetanus following smallpox vaccination gave us such readily applicable means of prevention that this complication practically has ceased to trouble us. But scarcely had tetanus passed out of the picture when encephalitis took its place. It has been of rather minor importance in the United States but abroad it has had to be taken more seriously. Everywhere that this distressing complication of vaccination has made its appearance

there has been advanced to explain it a relationship of coincidence between the complication and the prophylactic procedure; in other words, an ordinary case of lethargic encephalitis had chanced to afflict someone recently vaccinated against smallpox. The accumulation of hard, cold facts has made it necessary to revise this comforting view and, so far as I know, no one now denies that post-vaccination encephalitis is a direct, though rarely occurring, sequel of vaccination.

Perhaps it is hardly necessary for me to say that I am an orthodox believer in smallpox vaccination, but I am willing to admit that rarely it is the cause of serious complications. These do not occur frequently enough to make it necessary to modify the doctrine of general vaccination. But the fact that they do occur is sufficient to stimulate us to take every means at our disposal to prevent them. Indeed, with respect to encephalitis, the studies already made have shown that, for all practical purposes, it may be avoided by the practice of vaccinating in the first year of life. We are beginning to be more circumspect in the use of prophylactic serums on account of the hazard of serum sickness or the more serious results of the administration of foreign proteins.

Evidence of the high esteem in which the laboratory worker is held by his colleagues in clinical and in administrative fields is to be found in the readiness with which his discoveries are received, and the promptness with which they are put to practical use. I am not one of those who subscribe to the doctrine that the results of research do not find prompt adoption. My complaint would be rather that the research worker often is not given time enough to perfect his material or his procedure. I happen to sit at a desk to which come many requests as to where materials still in the experimental stage may be

secured for public health application. In these days of widespread publicity of scientific information and of alert clinicians and administrative officers, one is likely to hear first of some advance in sciences relating to public health by a request that the material or the method be made available for general use. This is sometimes rather embarrassing to the research worker, and I have the suggestion to make that embarrassment might be avoided by rather strict deliberateness in passing out to the world the results of research. Indeed, I do not know of any substantial advance that would be sacrificed if the research worker would follow Jenner's example and refrain from publicity until his prophylactic or therapeutic measure had been well tried out. I fear that many of us are tending, too frequently, to announce publicly the results of immature and of incompleated observations. How many "preliminary notes" are published in our literature without any subsequent articles appearing?

A source of embarrassment in dealing with my subject lies in the overlapping of the frontiers of chemistry and of physics and of the biological sciences including bacteriology. Lest I be thought unappreciative of work in fields foreign to my own, I may say that in my own judgment the greatest advances in the field of medicine, including public health, since the discovery of anesthesia, have been made by Pasteur, a chemist, and Roentgen, a physicist. In respect to chemistry as applied to the field in which we are interested, perhaps more progress has been made in studies on the very minute. Witness studies showing the influence of extremely small amounts of heavy metals on metabolism with special reference to nutrition. Perhaps equally great progress has been made and is being made in the isolation and in the study, in pure state, of the group

of substances we know as vitamins. We are beginning to look to chemistry for advances in the studies of substances responsible for the activity of the so-called ductless glands. Chemistry as applied to bacteriology also is opening fields that give promise of much in the future.

Anyone may see that one of the trends is toward the description of new clinical entities—rather, it would be more accurate to say, the identification of clinical entities that have been with us for a long time, as tularemia, undulant fever, the eastern type of spotted fever, and psittacosis. Laboratory studies have made the recognition of all of these possible and have gone a long way toward making their prevention or control feasible.

Perhaps the most striking activity of recent years has been in the field that deals with the viruses. It is gratifying to observe the progress we have made in this field. We have come to realize that we can learn a great deal about an infectious disease without the cultivation of the etiological agent outside the animal body. We have not certainly cultivated the organisms of smallpox, of psittacosis, and of members of the typhus-spotted fever group; yet we have enough useful information to enable us to control them as well as, or better than, we do many diseases the etiological agents of which have been grown.

I regret that I am not able to bring to you, in behalf of laboratory workers, any noteworthy advance in relation to the diseases that bulk so large in mortality and morbidity. Cancer, tuberculosis, pneumonia, nephritis, and heart disease continue to take their toll in spite of our best efforts to learn how to prevent or how to cure them. Perhaps the new orientation now going on in biologic research may lead us to a better understanding of these and of many other diseases.

Let me now sum up my conception of activities and trends in the laboratory field: We are in a new era in which we must pay more attention to what, for want of a better expression, we may call intrinsic changes in micro-organisms. We are finding fruitful fields in the re-study of problems that we thought to have been satisfactorily solved by the pioneers in research work. We are reappraising agents and procedures, giving more attention to clinical and field observations than in the past. We are becoming more critical in the use of prophylactic and therapeutic agents, lest in any individual case we do harm. We are identifying new clinical entities and find that this is not necessarily contingent on cultivation of the causative organism. Finally, we are looking to the general biologist, the physicist, and the chemist for an increasing measure of help in the study of our problems.

Current Preoccupations of Health Officers.*

HUNTINGTON WILLIAMS, M.D., DR.P.H., F.A.P.H.A. (*Life Member*)
Commissioner of Health, Baltimore, Md.

THE most important matters before health officers at present seem to group themselves under three main headings: (1) the paramount problem of budgets in this period of economic uncertainty; (2) the need for careful evaluation of public health practices for the purpose of eliminating less profitable services and strengthening those of major health importance; and (3) a *practical* program which will bring the members of the medical profession into active participation in the community-wide application of personal hygiene. Please note the word *practical*, for there has been a lot of theory and lip-service in this matter.

A consideration of the first and second of these major preoccupations of the health officer might well go hand in hand, for during the golden decade from 1920 to 1930 health department budgets were almost constantly on the increase. Much of what was asked for was appropriated, and there was little or no necessity for pruning or eliminating wasteful practices or age-old inheritances that did not produce results commensurate with their costs. City, county, and state health budgets have recently been cut, in some instances by 20 per cent or more. To be compelled to go through such an experience may, I believe, be an intensely profitable one for a health department. The gains

resulting from such budget cutting, if not continuous or excessive, are sometimes unexpectedly helpful.

A health officer faced with a major appropriation reduction at first feels that it simply cannot be done. After the first shock is over, he sets himself resolutely to the task of pruning, which proves in the end to be a test of himself, of the department, and of its relationship to the governmental administration. Happy is the man at such a time who has the whole-hearted support of his superior officers and their genuine interest in preserving a fundamentally sound and efficient public health service. He is either free or not free to make the adjustment in the best interests of the community. He is either instructed to make the slashes himself or it is done for him by the budget authorities. To submit health department budget requests for 1933 with slight reductions from the figures for 1932, in my estimation, is a wise procedure because of the present financial situation that makes necessary every possible retrenchment in governmental expenditure. Within the limits of public safety, no health department can now afford to ignore the importance of this necessity.

Reductions in health department appropriations, where they have occurred, have made imperative the careful evaluation of public health practices in order that services which were eliminated or reduced in volume might not be those producing a major health return. Not only is it a question of what

* Presented at the Ten Star Final Special Session of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

activities should go by the board, but more difficult yet, which members of the staff can best be spared. Problems of civil service and tenure of office for personnel arise to plague the health officer's midnight hours that should be given to restful sleep.

Fortunate are the health departments which have already been able to turn their major attention toward modern public health practice, which centers in the personal health of the individual citizen. In many places there are dead weights that must be lifted from the health machinery, weights that have been inherited from a program that often centered in complaint work and nuisance abatement.

The splendid services of protecting city water and milk supplies and providing proper community sewage disposal have become foundation stones which are now accepted and on which future progress in public health will be built. Nothing must interfere with their continued and efficient functioning but primary attention should now be focused on personal hygiene. This will make available on a large scale known methods of health protection for the individual. The wide application of such personal hygiene is now recognized as essential for any advance in civic health. The thoughtful health officer is preoccupied in determining which of the inherited services of the past he can profitably eliminate or reduce and what other activities he must embrace or strengthen if he is to avoid the risks of stagnation and well founded criticism.

In this change of emphasis many things will come to your mind. The need for better industrial hygiene, which is perhaps the most important of the untilled fields of public health; added emphasis on prevention of illness in the older age groups; increased attention to the mounting death rates for cancer, heart disease, diabetes, and accidental deaths; a new focus on methods

of integrating mental hygiene with the community health service; and back of all, a proper emphasis on the need for public health education in order to bring about the desired results—all these and others come into the picture of evaluating present health practices for the purpose of sound future development.

Leadership in health promotion is the function of a health department. It should organize and coördinate official and nonofficial agencies and make possible a far-reaching health machinery. No health department can do its job along modern lines without the active support of the medical profession. This support is needed and is expected by up-to-date health officers. Such work as the eradication of diphtheria, the reduction of the venereal diseases, and the adequate care of expectant mothers and of young children must rest largely in the hands of the practising physicians. A health department can do much to teach the public to seek such keep-well services from the medical profession. It should never hope to have a staff or clinic service large enough to carry on the needed volume of work itself. The practising physicians are the outposts on the firing line in the modern battle for better health and they should be considered by all as veritable public health agents.

This brings me to the third major preoccupation of the health officer and that is the establishment of practical methods for bringing the members of the medical profession into a more active participation in the community-wide program of personal hygiene. There has been a great deal of theory and lip-service in this matter during recent years. Nearly everyone recognizes the desirability of having the practising physicians feel that they are playing a real part in the modern health crusade. As a matter of fact, they are doing just that in a large portion of their private practice day by day, but

they have received very little recognition for their contribution. In certain places where community sanitation, including water and milk control, sewage disposal, and nuisance abatement vie with communicable disease control in occupying the major attention of the health administrator, the need for a more closely knit working arrangement with the local medical profession has not received due consideration.

Until recently some leaders in the medical profession have felt that public health was distinct and apart from private and personal hygiene and that the latter should be left entirely in the hands of the medical profession. Rather naturally those who are engaged in the great tasks of social welfare are somewhat impatient with any delay in the application of known preventive measures among large groups of citizens who are not able to take the initiative, or who will not, in the health protection of their own families. The fact remains that future advances in public health will be made largely in the realms of personal hygiene. The major portion of this gigantic task, if it be successful, must be performed by the rank and file of family physicians. There can be no more vital problems confronting the medical profession and public health authorities than their mutual relationships and fields of activity.

Sir Arthur Newsholme has published a valuable discussion¹ on the topic in a recent issue of the *Journal of the American Medical Association* and in his latest volume² *Medicine and the State*. Dr. William H. Welch, on the occasion of the celebration of his 80th birthday in Washington, in 1930, referred to this same problem and said:

Something of the lack of adjustment of the average man to rapidly changing social, economic, and political conditions of our complicated modern civilization, may be reflected in a certain temporary maladjustment

between curative medicine and preventive medicine, which should stand in harmonious relations.³

The adjustment needed to bring about smooth-running coöperation will perhaps be achieved when medical schools give the proper emphasis in their curricula to the teaching of the practice of preventive medicine; when dispensaries, clinics and health centers serve as foci for postgraduate medical instruction along preventive lines, and when health departments become fully awake to the valuable assistance which they may receive from the medical practitioners who are leaders in their own areas. Medical educators should keep ever before them the dictum of that statesman, Sir George Newman, Chief Medical Officer of the British Ministry of Health, who has said: "The first duty of medicine is not to cure disease, but to prevent it."

I keep thinking of an almost ideal situation where a health officer I once knew served as the chairman of the public health committee of his own county medical society. You may well imagine that cordial relations were almost inevitable in such a hook-up. It does not often occur. This rather dual personality would write himself letters from time to time, from the health department requesting the approval and assistance of the local medical fraternity on a particular health project. In due course of time the letter would be referred to the public health committee and he would send himself a reply assuring the health department of the desire of the local medical profession to do its best to assist in the particular activity under discussion. Some such working basis between health authorities and the medical profession is possible of achievement wherever it is sufficiently desired and where any pre-existing causes for distrust or suspicion have been removed. Many of you know of places where just such satisfactory

relationships have been worked out, by conference, by communication and by a little application from time to time of the Golden Rule.

It is my feeling that health departments must bring to the attention of the medical profession the fact that they, the health departments, are by statute required to do their utmost for the health protection of the public but, at the same time, that they desire to afford to the medical profession every opportunity of participating in the program and advising in the many details that will go to make it successful.

These details affect, in a very genuine way, the activities of workers in all of the sections of the American Public Health Association who are represented here today. After all, the health officer is merely the general family physician for the community who must call in the aid of specialists in the fields of laboratory work, of maternal and child hygiene, of communicable disease control, public health education, nutrition, and many other particular branches of service. In almost every

instance what these specialists would like to see in wide application impinges directly upon the private practice of medicine in any given locality. The Committee on Administrative Practice¹ states that satisfactory public health work requires among other things the support of the medical profession. This support cannot be had merely by wishing for it, but must be earned as a result of careful and unselfish planning.

In closing, may I say that health officers have no right to take themselves too seriously, that like others they must be able to give and take if their work is to succeed. If they are blessed with a lively sense of humor and a good digestion it is almost certain that their major preoccupations will not weigh too heavy upon them.

Work in Vital Statistics for Public Health*

WALTER F. WILLCOX, PH.D., F.A.P.H.A.

Professor of Economics and Statistics, Cornell University, Ithaca, N. Y.

WILLIAM FARR, who coined the phrase vital statistics, defined it as "the statistics of health, sickness, diseases, and death." But statistics, the numerical study of groups, can work only with definable, countable units. No such units of health or of

sickness have been established, and one may doubt whether they will be. In his later practice, which has determined English and American usage, Farr passed lightly over the statistics of health and sickness and centered attention upon deaths and causes of death, both of which are countable. While narrowing his definition on one side, he widened it on another by including not only deaths and their

* Presented at the Ten Star Final Special Session of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

causes but also births, marriages, and population, the last being needed to furnish the other term of the system of ratios or rates, death rates, birth rates, marriage rates, which make up vital statistics.

The subject assigned me is the major problems of vital statistics, with the aim of telling other students of public health what we are trying to do in the Vital Statistics Section. Our ultimate aim is, by use of the statistical method, to describe groups of human beings, measure the changes they undergo, and where possible ascertain the causes of those changes. In this description points arise which are of little interest to workers in public health. You might be told, for example, that in the United States the death rate of bachelors between 35 and 44 years of age is more than twice that of married men. If statistics can tell us also that this difference is due in part to a beneficial influence of marriage upon health and not entirely to the influence of marital selection, this descriptive statement would come within our Association's field, but even then it would be more important for biology than for sanitary science. What, then, does vital statistics accomplish for public health?

The aim of the American Public Health Association, as our Section views it, is to increase the degree of health and the amount of life in the American people or some group of them. But as health cannot be measured or counted, the vital statistician turns to measuring the amount of life in a given population, or, more specifically, the amount resulting from a certain number of births. This is found by multiplying the number of persons by the length of an average life. In this way vital statistics provides a marking system by which to gauge the success of the Association and also a goal toward which it should aim.

Until early in the last century students believed that the length of human life, one of our two factors, although greater in the days of the patriarchs, had been fixed in modern times by the fiat of the Almighty and that man himself had no power over it. Just over 100 years ago, Chadwick, in the teeth of the actuaries and out of the evidence they had supplied him, proved statistically that life in England averaged about 8 years longer than it had in the preceding century. He thus gave himself and others an attainable goal and made our Association possible. Neither he nor any later scholar has shown that the longest human life is longer now than formerly, but only that its average length is greater, this average depending mainly on the proportion of children born who reach or nearly reach the limit of age.

From the point of view of the length of life persons may be roughly divided into 3 classes: those who die before reaching the age of 10 years and who have been, economically at least if not otherwise, a burden upon society; those who live through the period of active life which ends perhaps on the average at about the age of 60, and those who die between the ages of 10 and 60. To a statistician the first of these 3 classes appear as failures, the second as successes, the third as partial successes. A comparison between the proportions of these 3 classes furnishes a measure of achievement in the work upon which our Association is engaged.

The death records of Massachusetts began earlier than those of any other state, and so that state has been chosen as an example. In 1930 those who died above the age of 60, the successes, were more than 51 per cent of all deaths; in 1842 they were only 22 per cent; in 88 years the proportion of successes had increased about $2\frac{1}{2}$ times. The proportion of deaths under 10 years of age, on the other hand, the failures,

was nearly 40 per cent in 1842; in 1930 it was only 13 per cent. The failures fell in 88 years to one-third of the initial proportion.

The statistics of one foreign country, Sweden, deserve a moment's attention because they began in the middle of the 18th century and so enable us to apply the marking system over a period of 175 years, twice as long as the Massachusetts interval. In Sweden, in the middle of the 18th century, the proportion of failures was about one-half. In 1928 it was 12 per cent, only one-fourth, instead of, as in Massachusetts, one-third of what it was at the start. The successes at the start were less than one-fourth and are now more than 58 per cent, and thus they increased, as in Massachusetts, about $2\frac{1}{2}$ times.

These evidences of progress suggest that our Association's goal is to secure a normal lifetime for every child born by reducing the failures and the partial successes to zero. The goal may never be realized but the progress just demonstrated suggests that it may be further approached—how closely none can tell.

This measurable change illustrated from the statistics of Massachusetts and of Sweden and probably under way in all civilized countries gradually eliminates the influence of natural selection, that is, selection by the premature death of the unadapted, or what

has been called lethal selection. If progress is not to be checked or turned backward it would seem that society must develop other forms of selection, like selection for marriage or for parenthood, to play the rôle filled by lethal selection in uncivilized or semi-civilized groups. Whether that can be done, and if so, how, are questions upon which statistics may some day cast light, but which, at present, it has hardly begun to face.

The practical statistical problems of the immediate future in the field of public health, as I see them, center about so utilizing our resources as to secure the greatest increase in the amount of human life that can be obtained from a given amount of available knowledge, energy, and money.

If we attempted to estimate in dollars the value of human life and its changes in value with age, we would probably conclude that its highest value comes in early adult years. But if life be given a value to be measured only by its amount or length, it would seem to follow that the most valuable lives are those of infants. By saving the life of an infant we add on the average to the sum total of life more years than we can in any other way. If so a reduction of infant mortality is the most effective way of increasing life and postponing death.

The Public Health Engineer's Work*

ABEL WOLMAN, F.A.P.H.A. (*Life Member*)

Chief Engineer, Maryland Department of Health, Baltimore, Md.

NOT quite a half century ago, the American Public Health Association was holding its Annual Meeting in Washington. A considerable part of its program was then devoted to what we now call "sanitation." Some of the Washington newspapers, in referring to the meetings, spoke of "sanitation" as "a novelty of doubtful utility." It was the same meeting at which a certain Victor C. Vaughan and a George M. Sternberg were awarded the Lomb prizes, the former for a paper on housing for the working classes and the latter for an epoch-making contribution on individual prophylaxis against infectious diseases.

Today, 50 years later, we are asked to take stock of public health engineering, a new name for an old "novelty." I hardly know whether to view it as a decrepit science, as some of our co-workers hint, or as a babe in arms still starting out into virgin public health fields. I choose the latter because I happen to be of cheerful disposition and also an amateur student of historical error in prophecy on the part of newspapers. I believe, with the one-time Secretary of the Maryland Department of Health, who had struggled for years for decent water supplies and sewerage systems, that "sanitarians are certainly harmless; and they may be useful."

Even if the economic system is on its last legs and the machine age is totter-

ing, the engineers assembled in Washington this week give no indication of being concerned about it. For years they have accustomed themselves to the task of adjusting environment to the advantage of man. If supplying safe drinking water, removing wastes, protecting milk and other foods, has made it possible for people to live in crowded cities, the engineer is now busy devising ways and means, with the instruction and aid of other workers in the public health field, to eliminate those disabilities which have resulted from this same urbanization.

His field has undergone considerable change in the last 50 years, but his objective, the control of environment for the promotion of health and welfare, has remained rigidly the same.

The improvement of water supply, sewerage, plumbing, and garbage disposal to forestall the current "accidents" of disease, such as typhoid, cholera and dysentery, was the major objective of the sanitarian. The fruits of these accomplishments are too well known to need repetition. Their continued supervision and extension are, likewise, obvious tasks of profound importance for the future as our populations extend in area and in numbers.

The increasing competition for water supply by growing cities is occupying more and more of the attention of engineers. Vast legal battles for the life streams of many millions have been waged during the past 10 years. The attempt to avoid overwhelming sewage pollution of major streams has run parallel with the struggle for water.

* Presented at the Ten Star Final Special Session of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

Even today the sewage of well over 80 per cent of the urban population of this country receives no treatment.

Some people like to believe that the public health importance of water supply and sewerage has dwindled in the last 20 years, but the engineer sees each day an increasing problem in providing satisfactory sanitary facilities for all the people. The mechanics of procedure has been much developed since 1890, but the program of action is no less pressing today than then. Although preventable death is still a municipal crime, this homicide rate is still too high.

To the current technical and financial difficulties in this field, has been added the increased esthetic demand of the consumer, who no longer wants a water supply which has merely the superficial characteristic of liquidity. Instead he demands safety, brilliant clarity, low temperature, absence of taste, odor, and color, freedom of corrosiveness, and soft water for industry and the housewife.

The engineer now presumes to meet these requirements. He coagulates water with many old and new chemicals; he filters through sand, coal or zeolite; he pre-chlorinates, super-chlorinates, post-chlorinates and de-chlorinates; he adds lime to raise the pH and sulphuric acid to lower it; he adds lime to precipitate salts and carbon dioxide to dissolve them, he aerates to remove gases or to put them back in circulation; he adds activated carbon, bleaching clays, copper sulphate, and chlorine to remove tastes and odors. No self-respecting water organism can stand the routine assault on his vitality. Perhaps the job is finished, but no water works engineer knows it.

The financial difficulties in the water supply, sewage and refuse fields are more pressing today than ever before and real concern for extending adequate

sanitary facilities to the public is apparent. We have not yet placed these sanitary requirements foremost in municipal economy and have much to learn from abroad. Perhaps, when we can parallel the experience of the City Council of Berlin, of which Rudolph Virchow was a member for over 30 years, we may preserve the budgets for public health. But who can visualize Haven Emerson on the Board of Aldermen of New York City, Wilinsky on the City Council of Boston, or Vaughan on the City Council of Detroit?

As if to remind us that our task in this field is never done, some 15 years ago water was incriminated in the case of mottled enamel of children's teeth. On this week's program, fluorine in drinking water and mottled enamel are added to the engineer's discussions. Evidence of endemic occurrence of mottled enamel in the teeth of children in North and South America, Africa, China, and Japan is now abundant. The cause of this serious defect in children is now reasonably demonstrated to be due to excessive amounts of fluorine in water. A new technic for the detection of fluorine has been devised and this new public health engineering problem appears before you.

Recent analyses of 110 public and 75 private water supplies in Arizona show fluoride contents ranging from 0 to 12.6 p.p.m. The survey disclosed 45 towns or rural districts in Arizona in which mottled enamel of teeth is endemic. Severe incidence of the same tooth deficiency has been reported from Arkansas, Kansas, Idaho, Oregon, New Mexico, and South Carolina. Concentrations of fluorides above 2.7 p.p.m. have been found to be definitely toxic in water supply. Abandoning a public water supply to prevent the disability is not always easy or possible. Methods of treatment for the removal of toxic concentrations of fluorides,

are, therefore, now under investigation.

The engineer is increasingly concerned, however, not only with the prevention or elimination of disease "accidents," but with the more difficult job of raising the "physiological tone" of the people. The assaults of a mechanized environment upon the helpless public have forced public health action, even before the physiological bases for action have been fully clarified. In these instances, as in the earlier attack on polluted water, corrective measures for disabilities have been introduced in advance of their scientific proof. Dr. Welch pointed out, in 1897, that "it is fortunate that those who instituted the first public sanitary measures did not wait to find a thoroughly scientific basis for them."

In the same way, the engineer is now called upon to defend the individual against noise, odors, vibrations, darkness, and stagnation, although the exact physiological bases of attack against these concomitants of the machine age are still indefinite. The instinct of man to revolt against them forces action.

How to recapture the heritage of sunlight for man! How to provide a natural and beneficial atmosphere! What are the modern criteria of sane ventilation? How can we eliminate smoke so that the sun's beneficent rays may once more reach our children? What does the turmoil of the modern city do to us? How can we measure the amount and quality of noise and its physiological effects? How can we eliminate it? What are the deleterious effects of industrial gases and how can they be corrected and removed? What are the hazards in swimming pools and how can they be circumscribed? How can we keep our streams clean, so that the joys of rippling brooks may once more refresh our eyes?

These are the new problems of our group. They require a new terminology and a new set of measuring devices.

The engineers are busy attempting to measure the difference between the noises of opera and of "uproar." When Rosa Ponselle does a 77 on the new decibel scale of noise measurement, does it hurt us as much as or more than when the New York or Chicago riveter reaches a 77? How much difference is there between Rudy Vallee's record of 75 and the 60 of the flat wheeled street car? One recent technical reporter justly inquires, "Is it right for Gigli of the Metropolitan to do a 93, while the harbor tug blasts out a mere 73 and gets into difficulty with the Noise Abatement Commission?"

Once upon a time, before the canyons of our great cities were built, it was unnecessary to recapture sunlight for our children. It was theirs by natural right. This week in Washington, the engineer passes from the decibel of noise to the actinic ray of sunshine as blithely as he once shifted from the *B. coli* to the B. O. D. test.

Strange as it may seem, although Greta Garbo and Marlene Dietrich know just how far they may tempt the erythemogenic or tanning power of sunlight and still keep their contracts, it seems that the scientists now in session want a more objective measure of sunlight effect. One of the reasons for the demand is the ever increasing number of ultra-violet radiators sold for healing purposes. Getting the sunlight artificially, however, is only part of the task. The profession is measuring at first hand the loss of actinic sunshine in the modern city, effect of smoke, and the ultimate means of recovering some of the values of sunlight.

Indoors, the problems of light, heat, and ventilation are likewise pressing, and the groundwork for understanding is being laid. A large part of this week's program is devoted to the discussion of measuring, conserving, and supplementing the natural and artificial surroundings of man in home and fac-

tory. Here, too, the concern is not only with the prevention of hazards, but with the raising of physiological tone.

Although we are taught in any modern school of hygiene that sanitary progress should be symmetrical, it is the peculiar habit of communities to consider but one problem at a time.

The engineer, with added tasks, is attempting to follow, however, his age-old road toward the control of environment for the benefit of man. He believes, with Wyndham Lewis, that "community plumbing is one of the very modern fine arts. Like criticism, it is useful!"

Industrial Hygiene*

ALICE HAMILTON, M.D., F.A.P.H.A.

*Assistant Professor, Industrial Medicine, Harvard School of Public Health,
Boston, Mass.*

A SURVEY of the field of industrial hygiene during the past year shows the profound effect which the business depression has had, an effect to be deplored but also to be recognized as inevitable. It would not be reasonable to ask of industry now that it enlarge and improve medical and welfare departments or even that expensive alterations be made for the safeguarding of health. When men are being laid off by thousands and those retained are working half time or less, all available money must go into wages, unless, indeed, the conditions of work are such as to offer a clear and recognized menace to health.

However, although not much practical improvement can be looked for at present, the study of health problems in industry goes forward without halt; it seems that research flourishes especially well during a period of business depression. Perhaps the most absorbing subject has been, as it should be, industrial dusts, those with free silica first, but also asbestos, interest in which, as was true of silicosis, has been stimu-

lated by the excellent work of English experts. Many investigations and experiments have been published during this last year, dealing not only with the effect of these dusts on the human lung, but also with methods of estimating the dust contamination of the air, and methods of preventing it.

It is hard to say what subject comes next in order of importance. Perhaps it is industrial cancer, the study of which was undertaken in all the industrial countries at the request of the Health Committee of the League of Nations. Here again the English led, for industrial cancer of the skin constitutes a major problem in that country, while in others, notably our own, it is of minor importance. Nevertheless, the investigation of the subject in this country, with results largely negative, has added to our knowledge of the causation of this particular form of cancerous growth. For instance, one of the greatest drains on the English sickness insurance comes from the prevalence among makers of patent fuel, briquets, of a slowly developing skin cancer of low malignancy. The English make enormous quantities of this fuel, using hand work, by mixing coal dust

* Presented at the Ten Star Final Special Session of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

with a binder of gas-works tar. We do not make nearly so much, use a binder of petroleum asphalt, machinery instead of hand work, and do not have briquet makers' cancer. Mule spinning employs thousands of Englishmen and scrotal cancer is very prevalent among them—has been ever since vegetable lubricating oils were displaced by Scottish shale oil. We do some mule spinning, and exactly in the same way as the English, but we use refined Pennsylvania lubricating oils and the only cases of mule spinners' cancer we could find in this country were in men who had emigrated from Lancashire where they had already carried on their trade. To these few instances could be added a number of others but they are enough to show that the study is of interest, not only in revealing our freedom from a very troublesome occupational disease, but also in adding to the gradually accumulating fund of knowledge concerning the chemical nature of the carcinogenic factor in oils, pitches and tars. This factor has not yet been isolated, but the pursuit is being narrowed down, and the end of the chase cannot be far off.

Closely connected with this field is that of malignant growths caused by the action of radio-active substances. For many years it was a matter of common knowledge that the miners in the Schneeberg region of Saxony suffered to an amazing extent from pulmonary carcinoma. The cause was variously held to be the arsenic in the ore, the chronic irritation caused by pneumoconiosis, and the radio-activity of the dust in the mines. It was most puzzling, however, that on the other side of the mountains, in Bohemia, no such disease had ever been discovered. This last year, the mystery has been cleared up. An impartial and scientific inquiry into the Bohemian mines and the condition of the miners revealed the same prevalence of lung cancer as on

the Saxon side, and, since in Bohemia there is little pneumoconiosis, the cause seems to be established as residing in the proven radio-activity of the ore dust. In this country our contribution to the study of new growths caused by radiation has been very important. I need only refer to the work of Martland, who first described the cases of aplastic anemia with bone necrosis in women who had been exposed to the action of alpha rays from the swallowing of luminous paint, and more recently has been publishing reports of the development of bone sarcoma in those who, less severely poisoned, have lived on and now exhibit this other type of effect.

Judging by the attention it attracts, one would have to put chromic acid high up in the list of dangerous poisons, and yet we all know that its importance is insignificant; but the great growth of chrome plating has brought it about that many men are now exposed to chromic acid spray and this is one of the poisons that works conspicuously, producing injury that is not serious but is very easily recognized. The result is that enterprising members of the legal profession are able to make much undeserved trouble for manufacturers and to spread among workmen the idea that here is a very dangerous poison whose evident effects only mask the more deadly internal injuries. British factory inspectors report that no case of chrome ulcer undergoing carcinomatous degeneration has ever been reported, nor any case of constitutional trouble. The lesions are local always.

Among the old familiar poisons we have a few new developments. More cases of arsenical poisoning due to the use of insecticides are being reported as such use increases. In lead, we have much evidence confirming Aub's theory of the storage of insoluble lead phosphate in the skeleton and its mobiliza-

tion under conditions leading to a change in the hydrogen ion concentration, also confirmation of his therapeutic procedure based on this theory. Aub's latest pronouncement on the treatment of plumbism is as follows:

De-lead by the administration of acids and a diet poor in calcium, keeping it up for 3 to 4 weeks, then interrupt when the patient has lost appetite and feels poorly. Resume it, if necessary, then follow with a calcium-rich diet, to restore the calcium which has been lost in the course of de-leading, inasmuch as calcium and lead metabolism go together.

Coal tar benzene continues to be the subject of investigation, for in spite of all efforts at its elimination, it is still used to a considerable extent in industry. McCord has just issued a book dealing with benzene in all its aspects.

Hydrofluoric acid and the fluorides are coming into much greater prominence because of their newer industrial uses and of their use as preservatives of foods. Pickling of metals is now done with hydrofluoric acid; sodium acid fluoride and sodium silico-fluoride are added to laundry soap mixtures; and although ordinary ground glass is now made by sandblasting instead of etching with acid, all electric light bulbs are frosted by immersion in this acid. The French have of late described what they call "fluorisme," chronic poisoning with hydrogen fluoride, which they have observed in man and produced in animals, by prolonged ingestion of minute amounts or exposure to

the fumes. It consists in cachexia, rigidity of the spine, and fragility of the bones.

Looking at the field of industrial hygiene in general, two things impress one: The first is that, because of widespread poverty and unemployment, we must expect a much larger number of unwarranted or exaggerated claims for alleged injury to be brought against employers by workers. This is understandable, but unless it is vigorously opposed, it will lead only to the disadvantage of the working class, by discrediting laws passed for their protection.

The second is that, owing to this same cause, we must expect to see the loss of standards which is already only too evident, keep on for some time. Already we are forced to admit that it is better for a man or a woman to take employment at a wretchedly inadequate wage, or under conditions far from ideally healthful, than to join the ranks of the applicants for public charity. That unscrupulous employers will take advantage of this peculiarly helpless state of labor is to be expected, but even the scrupulous employer may well think that he would himself prefer to risk sickness rather than to face certain penury. Apparently we can do little now to stem the downward course, but surely we can be alert to sense the first signs of revival and then to begin at once to insist on a return to the higher standards of our prosperity, none too high, at any time.

Food and Health*

HENRY C. SHERMAN,

Department of Chemistry, Columbia University, New York, N. Y.

I AM asked to speak on "Food and Health" in behalf of the Food and Nutrition Section. Only recently, however, has this Section included Nutrition in its title.

The greater part of the work of this Section has had to do, at least until recently, with problems of the ways in which food may injure health; as, for example, by carrying pathogenic microorganisms, or through containing deleterious substances added as preservatives, as artificial colors, or as gross adulterants, or formed in the food as a result of its deterioration.

Until recently, such possibilities, that food as purchased by the consumer might bring him some direct injury, were the liveliest issues of most discussions of food in this Association and among health officers and students of health problems generally.

Near the middle of the history of our organization, such questions were very acute. That was a period in which some of the discussions of pure food problems may have generated more heat than light; but the debates of those years did lead both to the searching of hearts and to the study and development of scientific, technological, and administrative methods of food control.

When there had developed a sufficient degree of confidence in food control, the federal food law was passed. It has now been in operation just over 25 years and has truly worked a peaceful revolution in the relations between the producers and consumers of food.

The passage of the federal food law, and of the supporting state legislation which followed rapidly, was a triumph for those who had labored for "food reform," and it was also a result and an index of the trend of the times.

It meant, that the methods for scientific control of the food industries, as well as for the policing of their products through wholesale and retail trade, had been developed to a point capable of commanding the confidence of the leaders among both producers and consumers.

Primarily designed for the protection of the consuming public, the food laws also function as rallying points for standardization and advance within the food industries themselves. Correspondingly, the officials who administer the Food and Drugs Act find that they can exercise a more effective control by using more of educational than of punitive measures.

And in addition to this gratifying degree of coöperation between the scientific and executive representatives of the food industries and the agencies of governmental control, we have the far reaching and efficient forces of agricultural research—federal, state, and privately endowed—working constructively upon all sorts of food problems in the interest of producers and consumers alike. More and more, food problems are coming to be looked upon from the viewpoints of science and of community welfare.

In the present membership of our own organization and most of its standing committees, we find the food control official, the scientific expert who guides

* Presented at the Ten Star Final Special Session of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

the production and industrial technology of food, and the teacher and investigator from the college or university, working together in unified effort for the good of the community as a whole.

So thoroughly has the pure food idea been assimilated during the past quarter century, and so effectively have the principles of sanitation (as well as of fair dealing) been applied in the production, handling, and inspection of food in recent years, that in general the consumer may now safely assume that food products offered for sale will not contain anything directly deleterious to health—that not fear of fraud or active injury but intelligent use of nutritional resources may be uppermost in mind as one now thinks of food.

Thus, largely because of the very success of the so-called pure food movement, the center of gravity of the general problem of the relation of food to health has shifted from sanitation to nutrition.

And this has come about at a most opportune time, for recent research has developed unexpected and far reaching possibilities in the relation of food to health through nutrition. We have found some, at least, of the keys, not only to the prevention of deficiency diseases and the reduction of susceptibilities to many infections, but also to the advancement of positive health and longevity through the simple application of the newer knowledge of nutrition in the daily choice and use of our common articles of food.

Until recent years, the food chemist was in the embarrassing position that while he could analyze an article of food in almost any degree of detail the importance of the case might require, he had never attained permanent success in the attempt to nourish an experimental animal with any mixture of the substances which his analysis revealed. And, in fact, the purer the substances entering into such an arti-

ficial food mixture, the sooner would failures of normal nutrition appear!

It became evident that some further means of investigating food values was needed, and this was found in the use of experimental animals as laboratory reagents and instruments of research into problems of the chemistry of food and nutrition.

Once this broadening of their armamentarium of food research had become established, chemists were soon rewarded by a whole series of discoveries of substances absolutely essential to nutrition but whose existence was previously entirely unknown or only very vaguely apprehended.

These substances have been discovered in too rapid a succession for their physical isolation and complete chemical identification to keep pace. Thus it accidentally comes about that they go under the one group name of vitamins, whereas, in fact, they are not so related in chemical nature or nutritional function as the use of a common group name must necessarily tend to suggest. Hence, even at the risk of tiresome repetition, we must constantly emphasize the important fact that the vitamins are not related to each other and have so little in common that no one of them can take the place of any other one; that the vitamin problem is in reality a whole group of independent problems, each vitamin demanding separate consideration.

But the discovery of the existences and essential functions of the vitamins constitutes only the first step in this new line of advance of our knowledge of nutrition. For chemical research has rapidly pressed on from the qualitative study of the occurrence and functions of the vitamins to the quantitative investigation of the relative vitamin values of foods and the optimal relations of nutritional intakes.

And this has proved to have a broader significance, from the point of view of

the student of life and health, than merely that it represents the general present-day tendency for each branch of scientific inquiry to develop itself, so far as may be, into an exact science. This in itself would mean much for the best use of food resources in the interest of public health and social justice, but this line of research has also revealed an even more far reaching significance.

It has been found that, starting with an adequate diet and a normal condition of nutrition and health, it is possible to advance the average of the existing status of health and longevity by enriching the ordinary daily dietary in certain of its chemical factors, by such simple means as merely the shifting of quantitative proportions in which our everyday foods are consumed. And this comes about not only through a further reduction of early death rates but also through a material improvement of the life expectation of the adult.

Just which of the chemical factors essential to normal nutrition are concerned in this positive advance of the already normal status of health and longevity, and in just what degree the average life cycle may thus be extended, are problems which are still being studied and for the complete solution

of which there will probably be needed some years of further experimental research.

Meanwhile we may speak with confidence of a positive relation of food to health and longevity. The average of acceptedly normal health and longevity can be advanced by applying the newer knowledge of nutrition in the daily choice and use of food.

Such an advance of average attainment in positive health and in the life-expectation of the adult, does not necessarily imply anything unprecedented so far as individual cases are concerned. What we may confidently anticipate is that quantitative research in the chemistry of food and nutrition has here opened the way to the attainment by many more people of that full measure of health and well rounded cycle of life which only the more fortunate now enjoy.

And, so far as we can see, the contribution thus offered by chemistry through nutrition stands in no wise in rivalry with anything else, but can be added to the gains which are being effected through all the other aspects of the great movement for the advancement of human welfare through public health and individual hygiene.

Health Education*

IAGO GALDSTON, M.D., F.A.P.H.A.

*Director, Medical Information Bureau, New York Academy of Medicine,
New York, N. Y.*

WERE I to attempt to tell you what is new in health education, I would be obliged to reiterate most of what was said by the preceding

speakers, and to anticipate much of that which will be said by those who are to follow me. For it is the privilege and obligation of our specialty to make use of all that is established and newly discovered by the other divisions in the field of public health. And yet

* Presented at the Ten Star Final Special Session of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

there is a good deal that is new in public health education, concerning which I would like to say a few words.

Thus, we in the Public Health Education Section have discovered that we are growing up. There is a characteristic crack in our voice, and there is the suggestion of a sprouting stubble upon our figurative chin. We are approaching the state of adulthood. We have crystallized our years of experience and have begun to formulate basic principles affecting our specialty. We have issued texts, as is witnessed in the works of the Routzahns. We are even bold enough to venture into the psychological phases of health education, and to refine our knowledge in this field. We have learned not only how most effectively to impart facts, but how to make those facts motivate human behavior.

Even more encouraging than the discovery of our own growth is the recognition that others are discovering us too. The other sections of the American Public Health Association are becoming aware of our existence and even convinced of our usefulness. The exuberant enthusiasm with which our Health Education Institute has been attended bears witness to this. Evidently, there must be something of value in our doings, or else we could not have attracted from the membership of the American Public Health Association a student body four times as numerous as we had hoped for.

All of which is very good. Those who have paid close attention to the trends of public health have come to realize that we have about exhausted the possibilities of doing for people that can be done for them, and that the approaches, in fact are already success in this epoch in which, if further experimentation in health is made, the people of the sub-
vealed. All
substances

must be taught to do things for themselves.

The great epoch in public health whose end we have recently witnessed was characterized by the elimination of many heretofore dominant diseases by the agencies of public health legislation, and the employment of vaccines, sera, immunizing and sterilizing agents. During this period great things were done unto and for the people, who themselves contributed little or nothing. What had the population at large to do with the blotting out of smallpox, or of cholera, or of bubonic plague?

But now those diseases which were subject to such mastery have already so been mastered. Today we find dominant the degenerative diseases, and those diseases which affect the emotional and psychologic aspects of human life. If we are to succeed in conquering these diseases, it will only be with the conscious coöperation of the individual in the community. We cannot hope for a vaccine to eradicate the various dementias, or for an anti-toxin that will immunize an individual against unhygienic and irrational living habits.

Public health education must therefore prove an important agent in the armamentarium of the public health doctor of today and tomorrow. It is and will evermore be the task of health education to impart basic knowledge relative to the prevention of diseases and the conservation of well-being. It will also be our task so to fashion our instruction that men will be not only informed but also persuaded. This is as it should be. The progenitor of Hippocrates was Apollo, the god not only of medicine but of music as well. And we in public health education are dedicated to Apollo and his arts.

Trends in Public Health Nursing*

HELEN C. LAMALLE, R.N., F.A.P.H.A.

*Superintendent of Nursing, Metropolitan Life Insurance Company,
New York, N. Y.*

THE progress of public health nursing depends upon the acceptance of constructive trends that will make it possible for us to scrutinize our present program. You will agree that the time has arrived for a careful, critical analysis of actual performance in nursing practice.

As public health nursing is a community service, we have to keep in mind the changing social conditions, and modify our methods accordingly.

Having considered many trends in my study, I have selected three because of their importance to the field of public health and to public health nursing as a whole.

1. Trends with respect to nursing practice
2. Trends with respect to community relationships
3. Trends in the growing consciousness on the part of Health Officers as to the importance of communicable disease nursing

Let us consider first the trends with respect to nursing practice. As we obtain a better knowledge of communities our nursing service should be adapted to meet newly disclosed needs. All nursing is aimed at placing emphasis where it is most likely to do the most good.

Too much emphasis has been put on quantity rather than on quality. I think it makes for a better service if the family has more responsibility; if we try

to make every visit count, and to eliminate useless visits.

The goal is responsibility. There is a continual trend in the direction of preparing nurses for specific responsibilities.

Is it recognized that it is a legitimate function of organizations to provide training in service? to keep the staff alert to their opportunities? to have a continual educational process so that better service will result? Unless the principles taught through training are being properly applied routinely and systematically, then all efforts to effect the best service will be lacking in results. I think there is a much better understanding of this point.

Staff education is constantly growing and the best staff education is a continuous process. It requires frequent contact of the staff worker with the supervisor, who by reason of training and experience, is qualified to direct and aid her with her daily problems. The education of a staff nurse is not accomplished through introduction and initial demonstrations. It is a matter of months of careful instruction and constant supervision.

There is a trend that makes us conscious that no one is a good worker unless she is happy and healthy. She must be interested in her work before she can do good work.

Secondly, we will consider the trends with respect to community relationships. Some years ago only the very poor would use the nursing service, but

* Presented at the Ten Star Final Special Session of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

now the service is being asked for by a much better class on the part-time basis, and therefore the demand for service is increasing. We have with us not only the poor in increasing numbers but we have this new demand.

There is a trend toward generalization and amalgamation. There is much closer coördination toward building a community program. The economic situation is resulting in closer bonds between local health and social work agencies. Concerted efforts in fund raising encourage joint program planning. Some Community Chests have organized special advisory committees to help plan to meet changing conditions, and usually the public health nursing agency is represented. With the united forces collectively discussing their problems and combining their efforts toward the same aims and ends, we should have better equipped and more responsive agencies.

The third and perhaps one of the most important trends to consider is the growing consciousness on the part of health officers toward the need for nursing care to communicable diseases. Health officers in the past have generally not approved the inclusion of nursing care to communicable diseases in the general nursing picture. The program should provide more definitely for this, and for close and mutually advantageous relations between health officers and private organization nurs-

ing services. Every health officer has the leadership and authority to aid in developing a well rounded community program which will include a larger measure of nursing care to communicable diseases.

I have the privilege of representing a company which has established nursing service in more than 5,000 cities and towns. During 1931, the company spent more than \$4,000,000 for nursing service which made possible service to upward of 800,000 cases, and in the analysis of more than 200,000 of these only about 5 per cent were of measles, scarlet fever, whooping cough, diphtheria, and other communicable diseases. You will agree that this study reveals that relatively few cases of communicable diseases are being nursed.

I cannot help wondering how the large number of Metropolitan policy holders who were ill with communicable diseases fared during 1931. How much did lack of care and lack of knowledge on the part of these sick policy holders contribute to the spread of communicable diseases? How many are suffering from unfortunate effects which might have been prevented, simply by knowledge? It is impossible to contemplate this gap in nursing service without realizing that it may represent a large volume of serious incapacity as well as loss of life. Is not the stopping of this gap of vital importance to all interested in public health?

Current Work of the Section on Epidemiology*

HAVEN EMERSON, M.D., F.A.P.H.A. (*Life Member*)
Professor of Public Health Practice, Columbia University,
New York, N. Y.

IT is the proper rôle of youth to have no past, and to speak only when spoken to. On behalf of my colleagues may I say that the session of today seems to me symbolic of the spirit of the American Public Health Association in which the young and old discuss on the same level of purpose problems of common concern.

It is wholly fitting that the message and report of the Section on Epidemiology should come last on this program. Chronologically the youngest of the sections and functionally the final building stone in the structure of public health practice, epidemiology brings critical tests to bear upon performance, and establishes principles of procedure based upon exact information and mathematically valid inference.

Whether originating from the sciences of laboratory medicine, or engineering, or mathematics, or out of the disciplines of observational or clinical medicine, the epidemiologist is entitled to the distinction of a specialist in public health. In fact, he is a master of the natural history of disease as it expresses itself on groups of persons, related by some common factor such as age, sex, race, occupation, or geographic distribution, as well as by the development of disease.

Without necessarily being a practitioner of any of the basic sciences of medicine or sanitation he must be able to use them in arriving at his own objectives.

By familiar tests, epidemiology is not only a vocation, a career, an intellectual discipline, an administrative function; it is a science in so far as its theories and laws of disease performance are based upon the accumulated facts, and objective reasoning, and to an increasing degree upon planned experiment, both upon man and upon the lower animals.

And when the idea is firmly fixed in mind that epidemiology is more than the science of epidemics or of epidemic disease alone, and that its function is not solely to nose out the particular case of origin of an outbreak of communicable disease, then we shall have registered a step in advance in the conception of the qualities and performance to be expected of its devotees.

Epidemiology has lived long enough to have had its amateur and professional periods, its observational and its experimental phases, and it appears now to be firmly established as a discipline in education in public health, and as a controller of public health practice.

While Fracastorius in his *De Contagione* in 1450 made what is probably the first important contribution to the method of study and reasoning which we now assign to epidemiology, we must credit the teachers of vital statistics and

* Presented at the Ten Star Final Special Session of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

preventive medicine in Edinburgh, Glasgow, and London of the last 75 years with laying the foundations for the modern science and practice of this specialty. One society in England, now merged as a section under the Royal College of Physicians, the young American Epidemiological Society, and the Section on Epidemiology of the American Public Health Association, are to my knowledge the only formal organizations devoted to its cultivation and promotion.

After 2 experimental years with programs in epidemiological problems (1927-1928), the creation of the section was approved. A consideration of the separate and joint programs of the section offers food for thought.

Of the 59 papers presented (1927-1932), 11 have dealt with enteric disease, 7 with meningitis, 6 with diphtheria, 5 with tuberculosis, and 5 with syphilis. If one were to recall contributions of outstanding and permanent significance there would come to mind those of Jordan, and Collins, and Frost on influenza, Gordon on scarlet fever, Parran and Munson on syphilis, Rosenau, and Hervey, and Dean on typhoid, and Godfrey on diphtheria.

It would be my personal opinion that the influence of Gordon's studies in determining the safety of variable isolation periods for scarlet fever according to season and age of patient, and of Munson's on the individualization of epidemiological attack upon syphilis in its household or village manifestations will have most important influences on

the habit and thought, and on public policies in the near future.

Related we grow in strength and usefulness, apart and separate in our specialties we weaken and lose power. For this reason the declared policy and fond hope of the Epidemiology Section is to have at least 1 and preferably 2 of its allotted sessions each year with one or more of the other sections, the Laboratory, Health Officers, Vital Statistics, and Public Health Engineering Sections in particular.

If one were to point out the most fertile fields for the application of the epidemiological method to the study of preventable disease he would probably suggest that in diseases of occupation and disorders of nutrition the largest returns would come.

When the validity of each public health procedure is tested with the rigor which curative medicine has applied to the results of drug and other therapy, we shall find the epidemiologist of the department of health playing an increasingly responsible rôle not only in controlling communicable disease but in replacing tradition, superstition, and popular opinion by science in the administrative practice of public health.

Epidemiology is perhaps the most romantic and intriguing of the specialist vocations of public health, unless it be that of the public health nurse. Furthermore it is clear that among the disciplines of a complete education in medicine, epidemiology must be included.

NOTE. The paper presented at the Ten Star Final Special Session by James F. Rogers, M.D., Dr.P.H., Consultant in Hygiene and Specialist in Health Education, U. S. Office of Education, Department of the Interior, Washington, D. C., on Child Hygiene, was published in the November, 1932, *Journal*.

Suggested Procedures for the Presumptive Test in the Determination of the Coli-Aerogenes Group^{*}

C. T. BUTTERFIELD

Principal Bacteriologist, U. S. Public Health Service, Cincinnati, Ohio

THE concentration of members of the coli-aerogenes group of bacteria in a potable water has been recognized as a measure of the safety of the water. In attempting to determine quantitatively any specific organism possibly present in a mixed culture of bacteria, some differential medium which will indicate with a fair degree of accuracy the presence or absence of that organism is a primary essential.

As such a presumptive test for members of the coli-aerogenes group, the fermentation of dextrose with the production of acid and gas originally was recognized. Later it was observed that all of the organisms which produced this change in dextrose did not belong to the coli-aerogenes group and that a much smaller group of organisms which could ferment lactose with gas production included all members of the coli-aerogenes group. As Sir Alexander Houston has so aptly said, the test for the coli-aerogenes group is "the sheet anchor of the bacteriologist" and the fermentation of lactose is "the common ground upon which all water bacteriologists can meet."

During the past 15 years a large amount of information in regard to the

permissible concentration of members of the coli-aerogenes group of bacteria in potable waters has accumulated, based on a determination of the group by *Standard Methods* procedures with lactose broth as the presumptive medium. Epidemiological studies have indicated that when potable waters are free, to a certain extent, from coli-aerogenes bacteria as determined by these procedures, the consumer has also been remarkably free from water-borne diseases. The maximum concentration of these organisms which might be permitted in a water without an increase in the incidence of disease has not been definitely defined. Such determinations might indeed be hazardous to the consumer.

Numerous efforts have been made during this period to increase the efficiency of this presumptive test and thus reduce the labor and the time required for this determination. In general these efforts have been directed along two lines: (1) to add to the presumptive lactose medium some inhibitive agent which would prevent or restrain the growth of organisms that do not belong to the coli-aerogenes group without interfering with the development of any member of this group; and (2) so to reduce the nutritive ingredients of the presumptive lactose medium that the growth of

^{*} Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

organisms other than coli-aerogenes would be restrained.

The former procedure has been most productive of media that have been widely used, and the present discussion will be limited to a consideration of the results obtained with some of these restrictive media.

Bile and certain of the dyes and combinations of bile and dye, have been employed most extensively as inhibitive agents. At first, using these materials in lactose broth, widely divergent results were obtained. Thus Cumming¹ found that lactose bile very markedly inhibited members of the coli-aerogenes group, while other workers considered that it was preferable to, and more productive than, standard lactose broth in the determination of the group. Studies made subsequently have shown that different batches of bile and dye vary in their inhibitive properties. In addition, these studies have tended to standardize these products and the methods employed in their use. Levine¹⁰ has shown that bile in a concentration of 1 to 2 per cent favors the growth of members of the coli-aerogenes group, while in greater concentration it inhibits them. Ruchhoft¹³ has observed that hydrogen ion concentration of brilliant green bile lactose broth markedly influences its inhibitive properties, high concentrations making it more inhibitive to coli-aerogenes organisms, and low concentrations rendering it ineffective in restraining even the growth of Gram-positive spore-bearing bacteria.

On the basis of the information obtained in these studies and in others which are considered in the reports of the Committee on Methods of the American Water Works Association, Dunham *et al.*,³ Jordan,⁵ brilliant green bile lactose broth has been indicated for further study as a presumptive medium, using two standardized methods of preparation. In one the concentra-

tions were, bile 2 per cent and brilliant green 1/75,000, and in the other, bile 5 per cent and brilliant green 1/20,000.

Using these two broths and standard lactose broth as presumptive media, we have made comparative determinations on 39 samples of raw waters and 44 samples of effluents. Isolations in pure culture were made from all gas-forming tubes and the completed test was applied. The same confirmatory tests were applied in each instance, the only variation in the procedure being in the presumptive media employed.

In the analyses of the 39 samples of raw waters, the average most probable number of coli-aerogenes group organisms per c.c. was: with *Standard Methods* lactose broth 3,920, with 5 per cent brilliant green bile 3,570, and with 2 per cent brilliant green bile 3,300; or placing the results on a percentage basis and considering those obtained with standard lactose broth as 100 per cent, the 5 per cent brilliant green bile broth detected 90.1 per cent, and the 2 per cent brilliant green bile broth 84.2 per cent of the coli-aerogenes group organisms present.

From 44 samples of effluent waters, the average most probable number of coli-aerogenes organisms as determined by standard broth was 268, by 5 per cent brilliant green bile broth 94, and by 2 per cent brilliant green bile broth 99. Thus with samples from this source, with the results from standard broth taken as 100 per cent, the 5 per cent brilliant green bile detected 35.0 per cent, and the 2 per cent brilliant green bile 36.9 per cent. It was also observed that the per cent of positive presumptive tubes confirming was much greater for the brilliant green bile media than for *Standard Methods* lactose broth.

The results obtained indicated, as has been claimed, that brilliant green bile presumptives confirm in almost 100 per cent. However, they also showed,

with equal conclusiveness, that with the effluent samples the brilliant green bile media detected only one-third as many organisms of the coli-aerogenes group, rather than 90 to 95 per cent as has been claimed. The objection may be raised that the additional organisms detected by the standard procedure are not really members of the group, or that they have no sanitary significance. This may be true. However, this section of the group was represented in the evidence considered in the establishment of standards for safe water supplies, and consequently the use of brilliant green bile as presumptive media would be the equivalent of lowering the standard threefold.

While it is not possible in this brief paper to review the tremendous amount of research work that has been done with presumptive media containing brilliant green and bile, the data which

have been reported are in general agreement with the above results. Reference is made to the reports of Dunham, McCrady, and Jordan,³ Howard and Thompson,⁴ and Ruch-hoft,¹² for a review of such studies.

The results obtained by 15 research workers for the Standards Committee of the American Water Works Association, as reported by Jordan,⁵ are of peculiar value for three reasons: (1) the waters examined were from widely distributed sections of the country, (2) the media used at each laboratory were of approved formulae and were identical in each instance, and (3) the technique employed in the different laboratories was uniform. A recalculation of the results given in Table I of this committee report is presented in Table I to show the per cent of coli-aerogenes group completions obtained by *Standard Methods* confirmatory procedure when: (1) *Standard Methods* lactose broth, (2) brilliant green bile 5 per cent lactose broth, and (3) brilliant green bile 2 per cent lactose broth, were used as presumptive media.

It is observed that while the average number of completions obtained from the 5 per cent brilliant green bile is 71.6 per cent, and from the 2 per cent medium is 80.5 per cent, as compared with the standard, the individual results with waters from the different sources vary from 45.4 to 90.9 per cent with the 5 per cent bile medium, and from 56.3 to 95.0 per cent with the 2 per cent bile medium. This indicates that brilliant green bile media are not equally sensitive in detecting bacteria of the coli-aerogenes group in waters from different sources, being very markedly inhibitive in some instances and only slightly so in others. No doubt if the effluent samples were considered separately the results would be still more divergent. This also indicates that this medium is not suitable for a standard and would tend to ex-

plain, perhaps, differences of opinion which have arisen in regard to its value as a presumptive medium.

As it is recognized as essential to go at least one step beyond the fermentation tube to establish the identity of members of the coli-aerogenes group, every advantage is to be gained by using a presumptive medium which will permit the largest number of these bacteria to grow and indicate their presence.

Because of its application to the discussion which will follow on the parallel planting procedure, digression is made at this time to consider the use of brilliant green bile lactose broth as a confirmatory medium. In the report referred to above (Jordan),⁵ confirmations obtained by *Standard Methods* procedure and by direct transfer from the presumptive lactose broth tubes to brilliant green bile, 5 and 2 per cent, were compared. From the data presented in this report, using the standard procedure results as a basis of comparison, the completions obtained from these confirmatory procedures by each of the 15 workers are given in Table II.

It is observed that in most instances the confirmations obtained with either bile medium compare favorably with those from the standard procedure. In 4 cases—samples from Omaha, Indianapolis, Montreal, and Chicago—the number of confirmations obtained with the green bile media was definitely low. This would seem to indicate, if it were not for these exceptions, that the fermentation of lactose with gas production in the presence of certain amounts of brilliant green and bile constituted a satisfactory confirmatory test for the presence of members of the coli-aerogenes group. The exceptions indicate that other factors must be considered.

In this connection it must be borne in mind, as is generally accepted, that in order to place an unknown bacterium

in its proper genus, it must be in pure culture and some information must be obtained in regard to its morphological, cultural, and physiological characteristics. Frequently it is necessary also to consider its pathological features.

Without some such system for the differentiation of the bacteria, even greater confusion would exist in attempts at classification.

Based on this system, the established criterion for the allocation of bacteria as members of the coli-aerogenes group of "all non-spore-forming bacilli which ferment lactose with gas formation and grow aerobically on standard solid media," takes 4 of these primary characteristics into consideration. The suggested change limits the identification to one characteristic—the fermentation of lactose in the presence of

brilliant green and bile. This suggested criterion, to conform with the established standards, would imply the following assumptions: (1) that all coli-aerogenes group bacteria grow and produce gas in brilliant green bile media, (2) all spore-bearing lactose-fermenting bacteria, aerobic or anaerobic, fail to indicate their presence, (3) all organisms fermenting this medium with gas production are bacilli, and (4) all organisms producing gas in it are aerobes or facultative aerobes although they have been grown only under practically anaerobic conditions. While these assumptions are known to be subject to limitations, and adoption of such a procedure would seem to be at variance with sound bacteriological practice, the favorable results obtained might warrant the adoption of a transfer to brilliant green bile as an alternative confirmatory procedure in locations where it has proved efficient.

A parallel planting procedure designed to combine the advantages of the productivity of standard lactose broth with the restrictive qualities of brilliant green bile, by providing for the inoculation of tubes of each medium in parallel with duplicate portions of a sample, was suggested by Jordan.⁵ This procedure has been amplified by Jordan^{6, 7} in subsequent papers, and an interpretation of the sanitary significance of the results obtained based on a special arrangement of the coli-aerogenes group was suggested.

As the interpretation of this procedure is based on the consideration of each pair of tubes as a single unit and on the assumption that the inoculation introduced into each tube of a pair is identical, marked differences of opinion have existed as to the value of the results obtained. Discussions of this phase of the procedure by Frost, Reed and McCrady, which are appended to the last paper by Jordan,⁷ definitely set forth the fallacies involved in this in-

terpretation, and the statement of Dr. Reed that "It would seem to me impossible to hope to get any explanation of a combined result that did not carry with it an implicit assumption that logically destroyed the parallel planting procedure," leaves no room to believe that the procedure can ever be employed.

Furthermore, the published suggestions for interpreting results from a parallel planting procedure are made with respect to the assumed age of the pollution rather than to its quantity. All past evidence in regard to the safety of water supplies, as measured by the presence of members of the coli-aerogenes group, has been based on numbers. The principle of assuming that sewage pollution is unsafe in proportion to its assumed remoteness rather than its concentration may be dangerous, and it should be avoided at least until epidemiological evidence has indicated its soundness.

Since it is now recognized as impossible to interpret the results from a parallel planting procedure, the only part of the suggested procedure which is eligible for use is the confirmation of presumptive standard lactose broth tubes by transfer to brilliant green bile lactose broth. This might be utilized as an alternative confirmatory procedure. The factors which must be considered in adopting it have been discussed.

A new presumptive medium has recently been suggested by Dominick and Lauter.² It consists of standard lactose broth modified by the addition of methylene blue and erythrosine as inhibitive agents and brom cresol purple as an indicator. They present comparative results obtained on samples from 4 sources with this medium and with lactose broth which show very excellent agreement. They believe that this medium not only eliminates false presumptives but also provides a satis-

factory means of differentiation between the coli and aerogenes types in the presumptive tube.

Studies comparing the Dominick-Lauter medium with standard lactose broth have been reported by Leahy,⁸ Leahy, Freeman, and Katsampes,⁹ and McCants.¹¹ All of these reports come to favorable conclusions for the new medium.

To determine in a preliminary way the value of this medium in the examination of samples in this locality, comparative tests were made with it and standard lactose broth. The Dominick-Lauter medium was prepared in accordance with the specifications given by Leahy which he states were approved by Dominick. Two hundred and sixty-five standard portions from 53 samples from the same source were planted into standard lactose broth and into Dominick-Lauter medium. All gas-forming tubes, regardless of the amount of gas formed, were confirmed in accordance with the standard procedure. From the 265 tubes of standard lactose broth, 31 tubes confirmed as containing members of the coli-aerogenes group. From the same number of Dominick-Lauter medium tubes 7 confirmations were obtained. Of these confirmations, 6 were obtained from both media, 1 with Dominick-Lauter medium only, and 25 with standard broth only. This would indicate that with samples from this source the Dominick-Lauter medium was not at all efficient in detecting members of the coli-aerogenes group, being even more inhibitive than brilliant green bile.

Of the reported studies with the Dominick-Lauter medium, that of Leahy *et al.*⁹ should have the best comparative value as they report findings from the examination of 1,116 samples from 358 different sources. This article shows that the presumptive tubes in the Dominick-Lauter medium were confirmed in almost 100 per cent, and

that the total number of samples from which coli-aerogenes organisms were isolated was almost identical for the two methods. If the presence or absence of members of the coli-aerogenes group in each sample is considered, there were only 53 out of 1,116 samples, or 4.7 per cent, that yielded contradictory results by the two methods. However, as we have stated before, we are not particularly interested in the mere fact of the presence or absence of members of the coli-aerogenes group in a sample in judging the safety of a water supply, but are intensely interested in the concentration of coli-aerogenes organisms in the sample if they are present. Unfortunately it is not possible from the data given in this paper to determine the coli-aerogenes group indices of the samples. However, it is possible to compare the number of presumptive tests obtained with each medium which confirmed. This will serve to compare the efficiency of the two media although it is of no value in calculating the concentration of organisms in a sample. Such a summary of the confirmed tests obtained by each method has been prepared from the data given by Leahy *et al.*, and is presented in Table III.

The number of positive results obtained from the various dilutions was not even "approximately of the same magnitude for either method," since

TABLE III
SUMMARY OF COMPARISONS WITH STANDARD-METHODS LACTOSE BROTH AND DOMINICK-LAUTER MEDIUM AS REPORTED BY LEAHY. A. J. P. H. 21:11, 1931.

| Dilutions c.c. | Number of confirmations | | Deviation from Standard Methods | |
|-------------------|----------------------------|-------------------------------|------------------------------------|----------|
| | Standard Method | Dominick- Lauter Method | Actual | Per cent |
| 10 | 688 | 744 | + 56 | + 8.1 |
| 1 | 549 | 440 | -109 | -19.9 |
| 0.1 | 320 | 205 | -115 | -35.9 |
| 0.01 | 53 | 36 | - 17 | -32.1 |
| 0.001 | 17 | 16 | - 1 | - 5.9 |
| 0.0001 | 7 | 6 | - 1 | -14.3 |

variations of from 6 to 36 per cent occurred. In all concentrations except the 10 c.c. portions the deviations from the standard are negative. This is the reverse of the results ordinarily obtained and makes it appear that some abnormal condition affected the results from the 10 c.c. portions. It is in these larger amounts of sample that the greatest difficulties are encountered in making isolations from standard lactose broth. These results also show that while the Dominick-Lauter presumptives uniformly confirm, the procedure fails to detect a considerable number of coli-aerogenes organisms present in the sample.

It is realized that the standard lactose broth presumptive test is subject to considerable criticism because of the number of presumptive tests which fail to confirm. However, a moderate experience in water bacteriology, in particular with the determination of the coli-aerogenes group, has created a firm impression that the failure to confirm is not as a rule due to gas production by combinations of two or more bacteria working together, or even gas production by bacteria which are not members of the group but that many of the apparently false presumptives are made so by a failure to isolate and confirm the coli-aerogenes group organism after it has demonstrated one of its characteristic reactions.

Improvements in the technic of confirmation, of early transfer from the presumptive tube to confirmatory media, and the distribution of the inoculation on the confirmatory plates so that well isolated colonies, rather than massive growths, are obtained, has gone far toward the elimination of false presumptives. A pure culture must be secured before a satisfactory confirmation can be made. Thomp-

son¹⁴ and Ruchhoft¹³ have made a forward step in this direction when they advocated the buffering of standard lactose broth to eliminate the production of hydrogen ion concentrations lethal to members of the coli-aerogenes group. This procedure should be made standard.

While it is expedient to consider procedures which will reduce the number of false presumptives and lessen the work involved, it is not wise to adopt some procedure which will vitiate the results obtained and possibly endanger the safety of water supplies by covertly lowering the standards of purity.

RADIUM POISONING

THE excitement caused by the poisoning, or alleged poisoning, of a number of women engaged in applying a radium compound to watch hands and dials is well remembered. We understand the company was very liberal to the victims, and that new methods have been insisted upon which obviate the danger.

Quite recently the papers carried the story of a man who died from chronic radium poisoning said to have been the result of drinking a water which contained radioactive substances. The last number of the *J.A.M.A.*¹ carries the story of a man aged 52 weighing 110 pounds, who was admitted to the hospital in an extremely emaciated and anemic condition, and with necrosis of the jaw. During a period of 5 years he had consumed 1,400 bottles of a water which contained 2 micrograms of radioactive substance in each 2-ounce bottle. The expired breath of this man was radioactive. After death, examination of the bones showed the presence of radium in such quantities that photographic plates were affected, giving quite clear pictures of the teeth and some of the bones. The detection of radium was carried out by the electroscopic as well as photographic methods, both giving positive results. The skeleton contained 73.27 micrograms of radium, while the soft tissue contained only 0.39 micrograms. The conclusion is that radium salts or radioactive substances in general are detrimental to health and fatal to life when introduced into the blood stream, and that the use of foods or drinks containing radium salts should be prohibited.

Since the first reports of radium poisoning appeared, a number of studies have been made and the results published in journals devoted to pathology, industrial hygiene, etc. There can no longer be any question of the danger of the use of such substances, and it is equally certain that they should be under strict control and used only by experts. The advertisements of commercial firms, the rather wide use of

radium and of radioactive substances by the public, and by others who have little or no scientific training is a striking example of the old adage, "Fools rush in where angels fear to tread."

VACCINATION AGAINST SMALLPOX — OR NOT?

IN spite of the century and a third which has passed since Jenner demonstrated the value of vaccination against smallpox, and in spite of the many proofs of its power to prevent that disease, there are still many controversial questions which come up from time to time.

At a recent meeting in England, 3 papers¹ were read on the abolition of the compulsory infant vaccination laws. Two of the authors, Drs. Ledingham and Forbes, favored infant vaccination on a voluntary basis, while a third, Dr. Millard, maintained his attitude, held for some years, against vaccination. Dr. Millard apparently has no doubt of the protective value of vaccination against smallpox, but believes that we now have a type of the disease generally known as "variola minor," which leads to considerable confusion, but at the same time protects against variola major. He suggested that international complications which might possibly arise from such a course could be avoided by calling this variola minor, "alastrim," or "petty-pox."

Against this, McSweeney has published a study² of variola minor, in which he advised strongly against the use of such terms as "alastrim," "para-variola," "varioid," "modern smallpox," etc., as being liable to lead to confusion. He pointed out that epidemics of smallpox have varied in virulence ever since the disease has been known, the mild disease having been described in 1770, and again by Jenner in 1798, and believes that the present practice of the Ministry of Health in speaking of this mild type as "variola minor" is suitable as well as correct. He points out that it has never been disproved that variola minor can produce variola major, and urges the need of its control through accurate diagnosis, prompt segregation, vaccination, and the control of contacts.

It is known that the distinction between the two types of smallpox cannot always be made with certainty, the difficulty being especially marked when smallpox reappears in a district after an interval of freedom. Practically all textbooks point out the well known variations in symptomatology and virulence in smallpox, running from types in which there is a violent toxemia which is speedily fatal, to others in which the attack is extremely mild, with eruption absent and symptoms so mild as to escape recognition.

The question of alastrim has led to considerable confusion in administrative measures. In various countries it has been called amaas, alastrim, Cuban itch, variola minor and para-variola. The trend of modern authorities seems to be to use the term alastrim, which has become well known. The disease is clinically like smallpox, but with practically no mortality. Some have tried to separate the two diseases by symptoms, but without marked success, as the resemblances predominate, the rash showing the same distribution, appearing commonly on the 3rd day, though there is sometimes delay, just as there is, however, in smallpox. The eruption goes through the same stages, though it is said that the lesions are smaller and are more superficial. However, few can distinguish one disease from the other clinically. The whole process bears a close-resemblance to

variola and to varioloid, or smallpox modified by vaccination. It is agreed that vaccination protects against the mild form of smallpox, or as we have called it, "alastrim." The disease occurs practically entirely among the unvaccinated and, like smallpox, affects those under 15 years of age predominantly. Fortunately some tests, such as the allergic, in humans as well as in animals, Paul's test, animal inoculation and serological tests have been developed, and some writers urge that these be employed more frequently than has been the rule.

As far as the etiology goes, the only thing that seems to be positively known is that it is a filtrable virus. As far back as 1892, bodies were described which seemed to be characteristic of the lesions of smallpox and of vaccinia (Guarnieri, Monti, Pfeiffer, Clarke, Councilman, and others). In 1906, certain granules were described by Paschen, which could be demonstrated in the variolous lymph, child lymph, vaccine lymph, in the inoculated cornea of rabbits, and other vaccinal material. A number of authorities believe that these are the actual virus, or a phase of it, and there is experimental evidence to support this view.

From the practical standpoint, the much discussed question of compulsory vaccination against smallpox is most important. In England compulsion has been greatly damaged by the conscientious objection feature. In the United States a recent study³ has been made of the question. Only 10 of our states, with a population of approximately 32¼ million—slightly less than one-fourth of the total population—have compulsory vaccination, and in them the case rate is only 6.6 per 100,000. Six states, with a population of approximately 18 million, have local option, with a case rate of 51.3 per 100,000. Twenty-nine states, with a population of approximately 60 million, have no vaccination laws, and in them the case rate is 66.7 per 100,000, while in 4 states, with a population of approximately 4 million, compulsory vaccination is prohibited. The case rate in them is 115.2 per 100,000.

We have been for a number of years quoting the figures given in textbooks on hygiene showing the great difference in cases as well as deaths in countries with compulsory vaccination and those without. The figures just quoted are fresh and taken from our home population. Surely they do not need argument or elaboration to prove the value (1) of vaccination, and (2) of compulsory vaccination in childhood.

A NEW JOURNAL

THE first issue of *The Health Officers' World*, the official publication of the International Society of Medical Health Officers, dated January, 1933, has just made its appearance. It is under the editorial management of Dr. John P. Koehler, with Dr. James Roberts, of Hamilton, Ontario, as Associate, and published at 505 West Cherry Street, Milwaukee, Wis. It is proposed to publish 4 issues a year. The first number is largely taken up with explaining the reason for this publication, which is called a "bulletin" in some places. It is well printed. We wish the Society and its publication success.

Employed Boys and Girls in Milwaukee—In 1920, there were 4,617 employment certificates issued in Milwaukee to children of 14 and 15 years, and 1,190 to children of 16 years who went to work during school hours for the first time. Corresponding figures for the 12 months ended December, 1924, showed 1,926 and 1,080 certificates respectively. In 1925, there were 8,930 employed boys and girls enrolled in vocational schools from 14 to 18, inclusive.

Special tables show the nature of the first occupation and the occupation at the time of inquiry. In 1925, manufacturing and mechanical industries included 2,140 boys and 2,180 girls; transportation, trade, and clerical, 1,348 boys and 1,033 girls. (The report contains a considerable amount of statistical and other information concerning work relationships of these minors in a city where there are rather advanced regulations concerning the age and nature of employment and apprenticeship.)—Alice Channing, *Publication No. 213*, U. S. Children's Bureau, Washington, D. C., 1932.

E. R. H.

Division of Industrial Hygiene, Ontario Department of Health, 1931—In this *Annual Report*, the Workmen's Compensation Board referred for diagnosis, during the year, to the Division of Industrial Hygiene, 141 cases of alleged silicosis and 32 cases of lead poisoning.

Surveys were made of workers exposed to dust involving 450 examinations with X-rays in connection with grinding, polishing, porcelain manufacturing, moulding, and the preparation of abrasive cleaners.

A small group of workmen in batch rooms of glass bottle manufacturing were examined. These handled sand, lime, and soda ash. Despite the fact that exposure was high and for periods

as long as 9 years, only early lung changes due to silica were present.

In a group of 12 men preparing abrasive cleaner, all for 9 years or more, with heavy exposure to silica and alkali, there were but 2 cases of early silicosis and 2 cases of tuberculosis—1 of them moderately advanced after 17 years. "The findings in these groups suggest that simultaneous exposure to silica and alkali can take place without the rapid development of silicosis which has been reported elsewhere."

Workers exposed to a high concentration of gypsum dust showed no increased fibrosis of importance. Of 8 men exposed to asbestos dust, 3 showed minor lung fibrosis and 1 moderately advanced with no tuberculosis—the longest exposure being 11 years.

Benzol poisoning in the process of doping in patent leather manufacture resulted in 2 deaths and 2 cases with recovery; 3 workmen suffered minor effects; concentration of benzol in the dope as used was 47 per cent.

Bakelite dust, a condensation product of phenol and formaldehyde, showed no abnormality in eye examinations. Perionychia was observed in girls plucking chickens.

The 6 major causes of death—heart disease, tuberculosis, cancer, accidents, pneumonia, and Bright's disease—should be investigated, not in hospitals and clinics, but among comparatively well people, for whom plant medical service provides an opportunity.—J. Grant Cunningham, pp. 47–49 (see citation above), 1932. E. R. H.

Cautionary Notices—The British Department of Factory Inspection provides a considerable series of official cautionary notices to be displayed in workplaces and explained to employees. The following are examples:

Dermatitis (Form 367, April, 1928)—A placard illustrated with two half-tones; prevention, removal of stain from the skin, cure.

Dermatitis (Form 355, May, 1928)—A general notice describing dermatitis, its ordinary prevention and cure.

The effects of chrome on the skin (Form 398, Aug., 1930)—Chrome holes, chrome ulcers, precautions, dermatitis, effects on the nose, a recommended ointment, also a recommended nose wash.

Effects of lemon and orange peeling on the skin (Form 396, July, 1931)—"Acid holes" from the juice of these fruits, preventive measures before, during, and after work, recommended ointment, also water-proof plaster.

Hides and skins regulations, 1921 (Form 982a, Jan., 1922)—Warning to workmen concerning open cuts, scratches, pimples, etc., sticking plasters, care of hands and nails, food, and clothing.

Anthrax (Form 410, Jan., 1932)—Large placard carrying 9 reproductions in color of the development of anthrax infection in the skin from the first to the fifth days, with a description of the disease, its source, precautions about breathing and swallowing dusts of infected materials, and use of serum; also, addresses of agents supplying serum.

Celluloid fire dangers (Form 987, Jan., 1928)—Warning to workers and methods of control.

Carbon monoxide (CO) poisoning (Form 932, Oct., 1931)—Description of the gas, sources of poisoning, symptoms, first aid, artificial respiration by the Shafer method, with a reviving apparatus (illustrated).

Dangers from gassing or burns (Form 395, Jan., 1927)—Chemical regulations, breathing apparatus and life-belt, symptoms, general treatment; special treatment in the case of nitrous fumes, chlorine, sulphurous fumes, sulphuretted hydrogen, benzene and similar volatile bodies, carbon monoxide or producer gas, carbon dioxide. Also, how to apply artificial respiration by the Shafer method, with oxygen apparatus. Also, chemical burns of the skin and of the eye. Splashes of anilin or nitro-benzene.

The above may be secured at a price of a few cents each from the British Library of Information, 270 Madison Ave., New York, N. Y. E. R. H.

The Equivalent Temperature of a Room and Its Measurement—The author proposes the name "equivalent temperature" for the combined effects of dry-bulb temperature and radiant temperature present at any particular

point, and gives a description with illustrations of the eupatheoscope, a form of radiometer devised to record this combined or true temperature.

The author finds that neither the kata-thermometer nor the effective temperature renders a true report of the sensation effect as found by the eupatheoscope. The eupatheostat is an automaton for regulating the heating of a room or space.

With the instrument, the author finds that, at 65° F. equivalent temperature, the average skin temperature is then accurately 75° F. A sedentary worker, with his output of 17½ B.t.u. per sq. ft. per hr., finds comfort in an equivalent temperature of 65° F., while a man engaged on light industrial work may lose heat at twice this rate and be comfortable in an equivalent temperature of 55° F.—A. F. Dufton, *Technical Paper No. 13*, 9 pp., Building Research, H. M. Stationery Office, 1932. Procurable from British Library of Information, 270 Madison Avenue, New York, price 6d net. E. R. H.

Cyanide Poisoning in San Francisco—After describing 3 case reports illustrating the unsatisfactory methods now empirically followed in the emergency treatment of acute cyanide poisoning, a new treatment was used at the Park Emergency Hospital, which undoubtedly saved the life of the young man in question.

On September 5, 1932, the victim was brought to the hospital by friends who stated that he had taken poison and told them of it immediately thereafter. On admission he was comatose; showed spasms of the voluntary muscles with moderate opisthotonos and extreme hypertension of the hands and feet, the pupils were contracted and sluggish in their reaction to light; respiration was slow and regular. There was a bright vermilion hue to the lips and a peculiar odor (simulating

paraldehyde or chloral) of the breath. Gastric lavage with sodium bichromate was begun. The washings had the odor of cyanide.

An intravenous injection of 50 c.c. of a 1 per cent sterile aqueous solution of methylene blue (methylthionine chloride, U.S.P.), was begun. "Within a very short time, voluntary movements were noted, and before 5 minutes had elapsed, the man was conscious and appeared to be essentially normal except for a severe chill and an apparent flushing. Recovery was complete within 15 minutes."

An analysis of the gastric content corresponded reasonably closely with the patient's statement that he had taken 15 grains of potassium cyanide in about 4 ounces of water.

The use of methylene blue and other dyes in the study of biologic oxidation and reduction processes is not entirely new. Warburg began an extensive study years ago, publishing reports as early as 1910, and is still investigating the subject. The favorable reaction noted in animals by others prompted Hanzlik and Leake to recommend this treatment.

There is also evidence in the literature to warrant the use of methylene blue in carbon monoxide poisoning.—J. C. Geiger, *J.A.M.A.*, 99, 23:1944-5 (Dec. 3), 1932. E. R. H.

"Pneumoconiosis"—This is a special bibliography of works published up to December, 1931, on the general physiology and pathology, clinical pathology, and radiology of pneumoconiosis. The publication is intended as a preliminary step leading toward the compilation of a full bibliography.—Procurable from World Peace Foundation, 40 Mt. Vernon St., Boston, Mass. E. R. H.

"Occupation and Health"—Brochures No. 303 to 315 in this

Encyclopaedia of Hygiene, Pathology and Social Welfare, have now appeared, completing the subjects to be covered through the letter "O."

This group of Brochures includes the following: Paper Industry, Perfume and Essence Industry, Phenols, Photo-Engraving, Seamen (Pathology and Hygiene of), Silos (Work in), Sodium, Straw, Sulphur, Tantalum, Ultramarine, Vocational Guidance and Selection, and Welding, Autogenous.—International Labour Office, Geneva, 1932. Procurable from the World Peace Foundation, 40 Mt. Vernon St., Boston, Mass. E. R. H.

Alternating Current Precipitators for Sanitary Air Analysis—

1. An inexpensive precipitator unit.—Philip Drinker.

By the use of a luminous tube transformer intended for operating neon signs a simple inexpensive electric precipitator has been built. The total cost of this precipitator is slightly less than \$30.

2. Acid Formation in Electric Precipitators.—W. G. Hazard and T. Ishikawa.

The authors found that acids of nitrogen were formed in electric dust precipitators when the voltage, rate of air flow and tube diameter were within certain limits. This may invalidate determinations when chemical methods of estimation are used. Adjustment of the previously mentioned factors will serve to eliminate the errors of acid formation. *J. Indust. Hyg.*, XIV, 9:364-370, 1932. L. G.

Toxicity of Dichlorotetrafluoroethane—Dichlorotetrafluoroethane ($\text{C Cl F}_2 \cdot \text{C Cl F}_2$) is one of the newer chemical compounds which, because of its properties, is suitable for use as a refrigerant gas. In the present study dogs and guinea pigs were exposed to 20, 15, and 14.16 per cent concentra-

tions of the gas in one of the gassing chambers of the U. S. Bureau of Mines. On exposure to the 20 per cent vapor, generalized tremors, intermittent convulsions and finally exhaustion took place, while the exposure to 15 and 14.16 per cent concentrations caused some incoördination, generalized tremors, and occasional convulsions, which disappeared after three to five exposures to the gas.

With cessation of exposure of dogs to the 20 per cent concentration for a single 8-hour period rapid and complete recovery took place; death followed longer exposures than this. Guinea pigs, on the contrary, were not seriously affected by four 8-hour exposures or one 24-hour exposure to this concentration of the vapor.

In contrast with the 20 per cent concentration the 15 and 14.16 concentrations led to the development of a high degree of tolerance in dogs after three or five consecutive 8-hour daily exposures. No deaths occurred during 21 consecutive exposures at this concentration. For details concerning the

blood changes and pathology the reader is referred to the original contribution.

It is concluded that dichlorotetrafluoroethane is an organic vapor of remarkably low toxicity.—W. P. Yant, H. H. Schrenk and F. A. Patty—U. S. Bureau of Mines *Reports of Investigations* 3185. L. G.

Protection Against Mercury Vapor Afforded by Cannister Gas Masks—Two charcoal filled gas-mask cannisters, three type N gas-mask cannisters and two charcoal filled respirator cartridges were tested to determine their protective efficiency against mercury vapor. The concentration of vapor was 42.5 p.p.m. by volume.

The charcoal filled cannisters had a life of 112 and 117 minutes, the three type N cannisters ranged from approximately 15–36 hours while the respirator cartridges has a life of only 2 minutes. Rest intervals increased the useful life of the cannisters.—W. P. Yant and C. E. Traubert—U. S. Bureau of Mines *Reports of Investigations* 3187.

FOOD AND NUTRITION

Soft Curd Milk—Hill in 1928 (*Bull.* 227, Utah Exper. Sta.) reported a test for measuring the difference in toughness of curds in cow's milk. Any milk with a curd tension of less than 30 gm. he called "soft curd milk" and all above 30 gm. "hard curd milk." This standard has been adopted by the New York City Health Department.

It has been suggested that soft curd milk is better tolerated by infants than is hard curd milk, and this is the report of an experiment carried out at Bellevue Hospital. Eighty-two infants, under 1 year of age, over 90 per cent of them under 6 months, were selected at random except that preference was

given to small and underweight infants. The infants received soft curd milk for a period of from 10 to 90 days with an average of 21 days.

After the milk had been in the infant's stomach for 15, 30, and 60 minutes, the size and consistency of the curds were compared with those in the curds from certified milk (boiled and unboiled), evaporated milk and breast milk. Contrary to previous findings by Hill, soft curd milk showed a higher percentage of hard curds than did boiled milk. The curds were softer than those after taking unboiled certified milk, about equal in size to those of boiled milk, but larger and tougher

than those of evaporated or breast milk.

In this group of infants receiving soft curd milk instead of ordinary certified milk, 54, or 65 per cent, gained weight at the expected rate of healthy babies. The average caloric intake for these babies was 61 calories per lb. Twenty-one babies lost weight and the average caloric intake was 51 calories per lb. The chief cause of failure to gain was vomiting and diarrhea. Soft curd milk was of no special value in preventing or treating vomiting and diarrhea. It was shown that soft curd milk has no decided advantage over other certified milks in its digestibility. The infants given soft curd milk needed a higher caloric intake than those given other milks—Herbert L. Elias, *Am. J. Dis. Child.*, 44:296 (Aug.), 1932.

The Antirachitic Potency of Eggs from Hens Receiving Massive Doses of Activated Ergosterol—Fifteen Leghorn pullets receiving a normal ration were used in this experiment. They were kept away from the sunlight and received the ration from January 20 to March 17. During the last week, the eggs were collected for testing.

On March 18, 2 per cent of cod liver oil which was contained in the ration was replaced by 2 per cent of maize oil solution of activated ergosterol. After the birds received this dosage of vitamin D for 6 weeks, the eggs were again collected for testing. The egg yolk oil from the pullets receiving the cod liver oil had a vitamin D coefficient of 0.7.

The substitution of an irradiated ergosterol 10,000 times as potent as the cod liver oil resulted in an increase of only 185 times in the antirachitic value of the egg, indicating that the birds did not transfer the vitamin to the yolk efficiently. During the administration of the ergosterol the pullets lost about 20 per cent in weight and the general appearance was poor.

On continuing the administration of 2 per cent of 10,000 \times activated ergosterol solution for an additional 44 days, a further decrease in weight and egg production was noted. Three birds died and only 43 eggs were laid. The egg yolk oil from the pullets receiving the ergosterol was administered to baby chicks at levels equivalent to 2 per cent, and to 25 per cent of cod liver oil. It was found to be less effective than 2 per cent of cod liver oil for preventing leg weakness in chickens.

Additional experiments are being carried out to determine whether the source of vitamin D available to laying birds determines the antirachitic value of the vitamin D that will be stored in the egg.—Francis G. McDonald and O. N. Massengale, *J. Biol. Chem.* 99:79 (Dec.), 1932.

Studies on Vitamin G (B₂) With Special Reference to Protein Intake—Most of the work on the nutritional treatment of pellagra has been in connection with vitamin G, following the work of Goldberger and his associates. The suggestion that protein bears a relation to this problem is responsible for undertaking experiments recorded here.

Vitamin G was prepared from ground whole wheat with extraction of 84.5 per cent alcohol by weight. The dried residue was incorporated in the diet so that 1 kilo contained the extract from 500 gm. of wheat. Protein at 6, 12, and 18 per cent levels was fed, the protein being derived in one series from casein previously extracted with alcohol and in the second from milk powder plus extracted casein. The only source of vitamin B, except that naturally present in the animal, came from the wheat extract.

In both series of protein variations the average growth increased with the protein intake, the differences between the 6 and 12 per cent levels being much

greater than between the 12 and 18 per cent.

An additional experiment on 6 per cent protein containing an excess of vitamin G as protein-free milk showed a much higher growth rate than any of the others.

The authors conclude that while pellagra conditions indicate symptoms of vitamin G shortage, the vitamin deficiency should not be regarded as the sole factor but that the relation of the protein supply should also be taken into consideration.—H. C. Sherman, and I. A. Derbigny, *J. Biol. Chem.* 99:165 (Dec.), 1932.

Vitamin C Content of Frozen Orange Juice—Stored orange juice has been tested both chemically and biologically to determine whether there is a deterioration of the vitamin in freezing, during storage, and whether atmospheric oxygen influences its stability in either process.

The extracted juice was prepared in 3 ways, in air and freezing under air head spaces, in nitrogen and freezing under nitrogen, and extraction in air and freezing under oxygen, the first 2 methods comparing with the ordinary commercial practice.

The juice of Florida Valencia oranges was placed in ampules, frozen and stored. Assays were begun shortly after the juice was frozen and then compared with the results obtained from the juice stored 10 months. One and one-half c.c. of the juice preparations were given daily compared with the same amount of fresh juice from reserve oranges, while another group received no vitamin C. The average survival of the negative controls was 26 days with symptoms of scurvy showing before 2 weeks. There was scurvy evidence on post-mortem. No significant difference in growth was observed between fresh juice or any of the 3 types of fresh frozen juices. There was no difference

between the tests using fresh frozen juice and that using the frozen juice stored for 10 months.

To determine the antiscorbutic potency of the preparations, 0.01 N solution of 2, 6-dichlorophenol-indophenol was used to titrate portions of the juice with this dye after neutralizing with sodium acetate. Titrations showed some difference between the juices frozen under nitrogen, oxygen and air respectively. The orange juice was further treated to isolate the reducing substances. The reducing concentrate was diluted with water so that 0.5 c.c. had a reducing value equivalent to 2 c.c. of orange juice as determined by titration. Glucic acid with a reducing property similar to that of hexuronic acid was dissolved in water so that 0.5 c.c. portion contained 2 mg. of the acid. By titration this amount was equivalent in reducing value to about 7 c.c. of orange juice. On feeding this amount to guinea pigs the animals on glucic acid as well as the negative controls developed scurvy; post-mortem showed all animals in these groups to have severe scurvy.

Another group received 5 c.c. of diluted orange juice concentrate. The orange juice and the juice concentrate groups were in excellent condition at the end of 5 weeks when the supply of juice and concentrate was exhausted. While the colorimetric titration in orange juice may be a useful guide as to vitamin C potency, there are apt to be present in plant material reducing substances having no antiscorbutic value.—E. M. Nelson and H. H. Mottern, *J. Indust. & Eng. Chem.* 25:216 (Feb.), 1933.

The Nutritive Value and Efficiency of Mineralized Milk—Whole milk mineralized with iron, copper and manganese was fed to male rats 21 days old. These elements were added as solutions of FeCl_3 , CuSO_4 , and MnCl_2

so that 30 c.c. of milk contained 0.5 mg. Fe, 0.05 mg. Cu, and 0.04 mg. Mn. The rats grew from 60 to 200 gm. in 36 days, or an average daily gain of 3.9 gm. which is similar to the gain made by rats on an ordinary ration. Only 2.25 gm. of milk solids were necessary to produce 1 gm. of gain in weight.

A similar experiment was made with pigs. Ten young Yorkshire pigs were used. A solution containing 50 mg. Fe as FeCl_3 , 5 mg. Cu as CuSO_4 , and 5 mg. Mn as MnCl_2 was added daily to the milk given each pig. Twenty-five c.c. cod liver oil were given once a week to insure vitamin D. The pigs were weighed every 4 weeks, and made a daily gain of 1.26 lb. over a period of 16 weeks. Only 1.97 lb. of milk solids were necessary to produce 1 lb. gain in weights, while 3.53 lb. of the standard ration were necessary for the same gain.

In this paper the authors have merely demonstrated the possible importance of mineralized milk in experimental work, and have suggested that if the mineralization of milk is to be used under practical conditions the simplest and most efficient method of supplying these elements must be worked out in the future.—A. R. Kemmerer, C. A. Elvehjem, E. B. Hart, and J. M. Fargo, *Am. J. Physiol.* 102:319 (Nov. 1), 1932.

Pasteurization of Milk Artificially Infected With Two Strains of *Brucella Suis*—Investigations of recent years have shown that cattle may be infected spontaneously or artificially with *Brucella* strains of the porcine type, that porcine strains may become established in the mammary glands of cows and be eliminated in the milk, and that *Brucella suis* may be isolated from the blood of undulant fever patients. The susceptibility of cattle and man to porcine *Brucella* suggests the possible occurrence of a milk-borne, porcine

Brucella infection in man, and emphasizes the importance of determining the thermal death time of different strains of *Brucella suis* in order to appraise the reliability of milk pasteurization standards in the prevention of these infections.

Reported studies on the thermal death time of *Brucella* strains indicate that a temperature of 140° F. for a shorter time than that presented for pasteurization renders *Brucella* non-viable, but indicate that porcine strains are more resistant than bovine or caprine varieties.

The authors have studied the heat resistance of two strains of porcine *Brucella* in samples of milk in cotton-stoppered tubes and hermetically sealed glass tubes. Samples of whole and skim milk in cotton-stoppered tubes with a content of *Brucella* organisms ranging in the various tests from 5,000 to 500,000,000 per c.c. were subjected to a temperature of 144° F. for 30 minutes. Samples of whole milk in hermetically sealed glass tubes with a content of 100,000,000 *Brucella* organisms per c.c. were subjected to a temperature of 144° F. for varying periods of time ranging from 2 to 30 minutes, and similar samples with a content of 500,000,000 organisms per c.c. were subjected to temperatures of 134, 140, 142, and 144° F. for the same time intervals.

Results of these tests show that the strains tested are more resistant to heat in cotton-stoppered tubes of milk than in hermetically sealed glass tubes. In the former, *Brucella suis* survived 30 minutes at 144° F. in milk containing 10,000,000 to 500,000,000 organisms per c.c. but the same period of time and same temperature destroyed *Brucella suis* in milk containing from 5,000 to 1,000,000 organisms per c.c. Both strains of *Brucella suis* in hermetically sealed glass tubes of whole milk containing 500,000,000 organisms per c.c.

were non-viable after 20 minutes at 140° F., after 15 minutes at 142° F., and after 7 minutes at 144° F.

The authors suggest that the resistance of the organisms in cotton-stoppered tubes may be due to the formation of a dry film in which the organisms survive, this film not being formed in the sealed tube.

It appears that the thermal death time is influenced by the degree of contamination.

The authors cite the work of other

investigators which tends to show that the number of organisms encountered in milk is relatively small in comparison with the massive inoculations used in this experimental work. The data obtained suggest to the authors that efficient pasteurization will prevent milk-borne porcine brucellosis, but they withhold final conclusions pending results of studies on commercial pasteurizers.—S. E. Park, Robert Graham, M. J. Prucha, and J. M. Brannon, *J. Bact.*, 24:461 (Dec.), 1932.

CHILD HYGIENE

PARENTAL EDUCATION AND CHILD HYGIENE

WE are reminded constantly that organizations and technics of themselves cannot accomplish results in the child health field. Application depends upon the knowledge and active participation of parents and children. This is well illustrated in the infant welfare movement in this country and abroad. The mothers have been taught by public health nurses, and with simply-worded literature, to take advantage of the public health facilities and apply them to the individual child.

Considerable advances have been made in the physical care of the child. It remains to extend the same principles to cover its mental development. In a most challenging recent book on parental education* Mrs. Gruenberg has laid down certain governing principles.

The most obvious and the most widely accepted educational service for parents has to do with the physical care of children. So completely has the present generation of adults accepted its dependence upon a variety of experts for assistance in the physical care of children that this kind of help is often

quite overlooked when people think of parent education. When a mother gets advice on her own diet while nursing her infant, that is all in the day's work for the nurse or the pediatrician. When, years later, she obtains from other adults (who have perhaps had more experience) counsel on the management of that same child, that is parent education. But in all essential respects the former is quite as much "parent education" as the latter.

Similarly we have accepted the lectures and radio talks and printed matter on the hours of sleep or the treatment of scratches and burns without labeling the valuable instruction as "parent education." We have merely taken such help on the common-sense ground that it enables us to do our work more effectively. There are better ways of managing our affairs, as parents; and we want to find out what those better ways are. We have accepted the principle, then, that everything helpful to such better ways is parent education.

The symposium which appears in this volume is composed of short chapters written by leaders in their respective fields and covers practically every phase of child growth and development, and the relation of the child to the home, school, and broader contacts of the outside world. If one has not been convinced already that parental education as an integral part of adult education

* *Our Children*, a handbook for parents, by Dorothy Canfield Fisher and Sidonie Matsner Gruenberg. Prepared and sponsored by the Child Study Association of America, 1932.

is vital to the physical and mental well-being of the child, a perusal of this book will remove any doubts.

As a background to this and similar efforts in parental education, it is enlightening to trace the history of parent associations in this country. This has been sketched in *A Contribution to the Theory and Practice of Parents Associations*,* which is a discussion based on a 5-year experiment made by the United Parents Association of New York City from 1925 to 1931.

In the foreword Mr. Lindeman cogently says that

... modern parents are perturbed because they find themselves incapable of exercising the functions of parenthood on the basis of either native equipment or traditional knowledge. They find that their very young children need a kind of attention which calls for new knowledge and fresh comprehension. They also discover that the influences which play upon their developing children in dominant fashion originate, not within the family group, but in the surrounding community and its institutions. The most important of these institutions is, of course, the school. Approximately twenty million American children spend from 4 to 8 hours each day away from home and at school. These hours away from home and family are filled with stimulations which combine to form the child's personality. Parents have come to realize that they can only become effective in their parental rôles if they understand and collaborate with the institution which plays so significant a part in the development of their children, namely, the school. But, how is such understanding to be acquired and by what means is such collaboration to be achieved?

An attempt has been made to answer this question by the experiment sponsored by the United Parents Associations of New York City.

In 1925 the Executive Committee of the United Parents Associations of New York City formulated the theory that this new knowledge would produce most desirable results in social action if it were disseminated in such a way that the two institutions most pro-

foundly influential in the child's development, the home and the school, felt its impact simultaneously. As a corollary of that theory, it followed that Parent-Teacher Associations should be a medium for "parent education." . . . It is apparent to any one who carefully studies the parent-teacher movement that it has potential possibilities for playing a significant part in our present complex civilization. But the problems connected with converting those potentialities into reality are not simple and are not to be solved by rule-of-thumb methods or mere common sense.

Where is the growing individual to find interpretation and integration? Some psychologists answer these questions by saying that only the parents' influence is sufficiently continuous to guide the child toward a philosophy and to resolve the contradictions in his environment; that the home is the only place where he can feel secure and retire from the world to refresh his powers.

But in too many cases today parents have no educational technic for undertaking this delicate adjustment. Too many parents for lack of training ignore the child's problems or meet his questions with indifference or hostility. The psychologists contend that such ignorance on the part of parents results in much of the maladjustment and unhappiness which are a matter of common observation in so-called normal human life today and that it is possible that many of the extreme neurotic and psychopathic conditions which send people to reformatories, insane asylums, prisons and divorce courts, may be traced to the parents' lack of understanding and skill.

A most important point is stressed in discussing the application of modern psychology to the formal education of our children. The report states that

... although it is true that to date the findings of modern psychology have not revolutionized our school systems, public or private, minor changes in theory and some changes in practice have resulted. All of these point to the necessity for parent education. It is becoming apparent to the professionals in charge that a narrow concept of education, designed largely to prepare children for material success and based on drilling them in facts, involves stultification of individual values and does not fit them for creative participation in the great variety of possibilities inherent in human life. Therefore, the course of study in the new type of "progressive" school is attempting to deal not only with facts but also with free expression and development of individual

* By Maria Lambin Rogers with a foreword by Eduard C. Lindeman. Printed for the United Parents Associations of New York City by The Curative Workshop, 28 East 21st Street.

interests and curiosities. This broadened conception of education requires that principals and teachers know the whole child, a desideratum made possible only through the interest and support of the educated parent.

Certain principles of method are laid down for the conduct of mothers' clubs or parent-teacher associations. These are listed as follows:

"The first of these was that the parents in each school form the logical groups through which to work inasmuch as group learning, when attitudes are to be changed, is more effective than individual learning.

"Second, the results of group learning register themselves automatically in the conduct of any institution of which the group is a functional part.

"A third principle was that the autonomy of these groups must be kept inviolate.

"A fourth principle was that such energies and powers as the individual possesses will not develop in a cramped atmosphere where values are rigid and authoritatively determined.

"A fifth principle was that leadership for every parents association should be drawn from the local community.

"A sixth principle was that such alert and well-trained groups exert the maximum influence in the community if united in a federation.

"A seventh principle was that the work of the federation should not duplicate the work of any other organization in New York City, where so many agencies are concerned with civic welfare.

"An eighth principle was that the policies and work of the federation should be guided by the experience of the experts in the field of social science and that it should affiliate with these experts and give them influence in every possible way.

"A ninth principle was that the federation should be city-wide in character and should be representative of all

the organized parents of the city, both in private and public schools. It has, therefore, accepted for membership Parent-Teacher Associations, Mothers' Clubs or Kindergarten Mothers' Clubs, organized in connection with any school, private or public. It has encouraged the representatives of the private schools to take as active a part in the central federation organization as is taken by the representatives of the public schools."

In laying out an immediate program for the next 5 years the United Parents Associations have grouped their activities under 4 main headings:

I. Coördination of the work of the member associations;

II. Establishment and maintenance of needed services;

III. Building of prestige for parent opinion;

IV. Conservation and evaluation of experience and study of community conditions.

Under the coördination of the work of member associations the following are mentioned:

"A. The School Lunch Committee is to continue with its present program until its objective of adequate school lunch service is attained, which should be within the 5-year period.

"B. The After School Athletic Center Committee is to continue its present program until its objective of adequate supervised play service for children of the elementary schools is attained, which should be within the 5-year period.

"C. Fresh studies of the type made by the School Lunch Committee are to be undertaken. Three promising fields for those studies are: 1. Health service in the schools; 2. Vocational guidance in junior high schools; 3. Mental hygiene clinics for elementary schools. As far as is feasible, preference shall be given to studies popular with the member associations.

"D. The Open School Week Committee is to continue its present activi-

ties. These are to remain a recommended project for member associations.

"E. Early Registration is to continue as a suggested project for member associations when the principal welcomes the help of the association in this work.

"F. A qualitative standard of admission for member associations is to be considered, covering the organization methods and program of activities of the association. These should probably be required to conform to the objective of parental education."

PUBLIC HEALTH NURSING*

Public Health Nurses Take Stock—All public services these days are having to give an accounting of themselves. Public health nursing is no exception. This accounting must show that the service is too valuable to be eliminated; also that the best quality of service is being given for the least possible cost.

The first problem then is to make the public health nursing service indispensable to the consuming public. The only way the public can know our objectives and the plans we have for realizing them is to share actively in a partnership service.

I saw an excellent example of this working partnership in a very rural county that had a nurse with unusual vision. For 3 years the service had developed under her leadership with everyone in the county participating actively—teachers, the P.T.A. groups, women's clubs, men's groups, children—all helping on some project during the course of the year. When a clinic was held for the removal of tonsils, for example, the local paper wrote it up as "our clinic" listing the people who had helped. That list was an interesting one, for it included almost everyone in the community, from the minister who was orderly, to the local physicians who coöperated actively, the teachers who scrubbed instruments, the women who assembled supplies, and the children who ran errands. The third summer while the nurse was away on vacation the bank failed in which much of the community's money was kept, and the county commissioners' meeting hurriedly decided to

cut all taxes for the following year as much as possible. Among other expenditures they eliminated the nurse's salary. When this was noised abroad the people protested, organized a citizens committee of the largest taxpayers to meet the commissioners, and finally succeeded in persuading them to put the nursing budget back in the county appropriation. This all happened, as I have said, while the nurse was away on vacation. Much to her surprise on her return she learned that she had lost and regained her position, but much more significant and valuable to her was the evidence that she had developed a real local leadership which would outlast her stay.

Our accounting should start then with a study of our methods and program of work in relation to volunteer service remembering that real progress in public health will come not through what we as professional people know and do but through what we can get others to do for themselves. We must give due credit also for the actual work which these volunteers accomplish. Few communities are able to afford enough public health nurses to develop an adequate program. There is so much that can be adequately done by intelligent lay people.

Every public health nurse should ask herself these questions:

1. What am I doing which does not necessitate a nurse's training?
2. How much that I do can safely be delegated to others?
3. Do I share responsibility for planning and joy of accomplishment?
4. Do I remember to make the work interesting and vital to volunteers?

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

The second problem, so magnified in these years, is to give the best quality of service for the least money.

The first question we must answer is:

Is our program based on community needs?

A recent investigator of nursing services reports that the majority of nurses whom she visited (picked because they represented current field practice) could not answer such fundamental questions as these in relation to their own work: the population of the territory served, the annual birth and death rates, the number of babies dying under 1 month and 1 year of age, the number of mothers dying from puerperal causes, the leading causes of local deaths, and the relationship of these facts to the nursing service. How can you justify the cost of your day's work to your community when you neither know the local needs nor are able to measure your accomplishments in terms of those needs?

The administration of the service must be justified also. Both the nurse and her lay board and committees must decide whether they can afford a highly specialized service to one special age or disease group or whether the service should be generalized service on a family basis with more economical administration, by having all similar groups coördinated in one organization.

The question must be answered. "Have all unproductive costs been reduced as far as possible?"

The nurse should lead the way in helping the community to see for what health needs they should provide and how far they fall short. The appraisal forms published by the National Organization for Public Health Nursing and the American Public Health Association set up standards for accomplishments.

How close does the community come to meeting these standards? What plan can we make for the next 10 years which will insure each succeeding year a service which will more nearly meet these standards?

Not only must the administrative and financial program be analyzed but the

professional details of each day's work need scrutiny. Does each visit of every day justify itself in results attained? Why are some families uncoöperative? How many repeat visits are profitable when our funds limit the extent of our service?

Do we study records in the light of our successes and failures and make plans accordingly? Do we plan each visit carefully and afterwards critically appraise it?

The public health nurses, more fortunate than other nursing groups, are better organized, more regularly employed and more accustomed to working with lay groups. They then should assume leadership in their communities in analyzing professional problems other than those involved in their day's work. Is your community aware of the oversupply and under employment of nurses? Are they making plans so that all those who are sick can receive the services of nurses who need work at a price satisfactory to both parties? Do high school girls know the facts about nursing as a vocation? Do teachers and vocational advisers know that only their best graduates are welcome in the nursing schools?

Certainly at no time than when we are facing problems like these have we greater need of our national organizations. The American Nurses' Association and the National Organization for Public Health Nursing are making studies, giving us standards by which to measure our accomplishments and fighting for rights which affect every one of us as individuals in a profession which is striving to develop an increasingly superior service.

They need our support in membership and in subscriptions to the magazines.

Out of this period of economic stringency, the nursing profession can, if it will, develop a quality of service far superior to that which it has rendered in the past; but it will ac-

compish this only as we all resolve to give to each hour of every working day the most intelligent, thoughtful quality of service that we are capable of—setting up within ourselves standards of work which will be satisfied only with our best, and developing a habit of planning, questioning, and measuring all that we do in terms of meeting the concrete needs of *our* community.

Katharine Faville, R.N. Problems in Public Health Nursing, *Pub. Health*, Michigan Department of Health, XX, 12:267-275 (Dec.), 1932. V. A. J.

Health Integration in High School—Public health nurses are always searching for ways of integrating health with other subjects so that they may give helpful suggestions to teachers. Especially precious are suggestions for integration in high schools where each special teacher has a particular angle from which she may approach health teaching.

Two helpful suggestions come from Great Neck, N. Y., a town of 5,000 people where everyone seems to be enrolled in the Health League, if not as a member at least as a coworker with the community public health nurses.

The teacher of sewing had a style expert from the city come out and talk to the girls on good taste in girls' clothes. The gym teacher called in an expert beauty specialist who told the girls that exercise and fresh air would give them sparkling eyes and red cheeks and that nothing was so ridiculous as a young girl trying to appear like a society woman—unless it was the society woman trying to appear a young girl.

These methods were effective because they conform to the principles of adolescent psychology. The high school boy or girl wants to know the truth, but he wants to make some investigation himself and then draw his own conclusions. These boys and girls want advice, but they do not want advice which is based on sentiment or which is threatening. There must be a clear, logical reason behind it. The adolescent is anxious for a philosophy which will

guide and direct his social activities so he may be popular and respected. He wants to be considered an individual with a personality of his own.

Health teaching based on these principles will likely receive the desired response in high school students.—

Inez Macaulay, Great Neck, N. Y., What Our Town Does to Keep Us Well. Frankwood E. Williams, *Adolescence*, 1930. D. A. Thom, *Normal Youth and Its Everyday Problems*, 1928.

V. A. J.

An Adequate Community Nursing Service—When the sick people in every rank of life in a community get good nursing care because all varieties of skilled, competent nurses have coördinated their work, that community may be said to have an adequate nursing service.

The medical profession and the general public, as well as the nursing group, must take a hand in the attempt to assure an adequate community nursing service.

Most people divide nurses into three groups, institutional nurses, private duty nurses, and public health nurses.

Private duty and institutional nurses often look on public health nurses as having more freedom because they have regular hours, Sundays free and a regular salary. They do not realize the mental strain involved in shifting from one household to another in the public health nurse's eight-hour day. "No really good field nurse can forget her patients just because the clock strikes four or five p.m." She cannot turn her patients over to a night nurse when she leaves the district at night. Hence she often keeps them on her mind and worries about them.

During the last few bitter years only the gratitude of the poor, the sacrifices that they so willingly make for each other, and the backing of a group of lay people just as eager as the nurse herself to ameliorate the lot of

the unfortunate, have enabled the public health nurse to carry her load.

Physicians and surgeons have been of little help to nurses in demanding minimum standards of good nursing. Nursing groups have been mostly to blame for this because they have not made the medical profession see how much nursing skill is required for certain treatments and how difficult it is to attain this skill if the student nurse has not been well instructed. Have nurses really been candid about sharing their problems with physicians? All good doctors want their patients to get the best nursing care obtainable and they also want the nurses to get a square deal.

One able surgeon who is on the executive committee of a nursing school stated that the best attending staff in the world did less to make the reputation of a hospital than the quality of its nursing service.

Nurses need better organization. Whether they do private duty, institutional or public health nursing, they should be organized under lay groups or advisory committees so that "the older nurse will be sent to those patients who need her special skill and experience, will be paid according to her ability,

and will not be expected to compete with the young graduate only a few days out of the hospital."

Behind most groups of public health nurses are keen, interested lay committees, and these committees have been able to work out standards of administration, promotion, standards of work, etc., because they were interested in having the sick poor and wage earners in the community get skilled nursing care.

Hourly nursing should be an appointment service operated by a local registry. Even private duty nurses should be organized through registries into groups graded according to their skill and experience and protected by lay committees.

Nurses must then have the backing of lay groups and physicians in making the cornerstone of their foundation the well equipped, well prepared nurse.

And nursing must show constantly such excellent results that a now somewhat inarticulate public will become vocal in its requirements for good nursing, just as a well organized community demands safe water, safe milk, or the finest type of teaching in its public school system.

Edna L. Foley. Providing an Adequate Community Nursing Service, *Mod. Hosp.*, XL, 1:83-86 (Jan.), 1933.

EDUCATION AND PUBLICITY*

A Correction—"The Full Endorsement of the Advisory Council"—In the February, 1933, *Journal*, we quoted from published statements about a New York Food and Health Exposition announced for April 3-8, 1933. Upon submitting the paragraph to the announced members of the Advisory Council we learned that the matter was under consideration only. *There was no authority for the published statement* which we quoted. Since then it has been decided not to form an advisory committee.

Survey of Health Education—The State Health Council of Indiana has a Survey Committee to encourage a comprehensive study of health legislation, leadership, and facilities. The various sections of the study will be carried on as personnel and funds are available. Progress has been made in the study of the qualifications of special teachers of health and physical education and of instruction methods, under the supervision of H. E. Moore, State Department of Public Instruction, Indianapolis.

The Volunteer Worker—Under this heading appears a tribute to the volunteer from which we quote two paragraphs:

In looking over our stock in trade and counting up our assets one thing stands out above all the rest; the fact that the foundation upon which the success of the tuberculosis movement has been built is the untiring endeavor and the unselfish expenditure of time and energy on the part of the volunteer workers.

Hundreds of volunteers; the leading business and professional man; the busiest mothers

and housewives; active members of Parent-Teacher Associations; Home Economic Clubs workers; Women's Clubs members; all organizations finding time to devote themselves to the betterment of their respective communities' health. They go to make up the township chairmen, the directors, the officers, and the members of the executive committees of our tuberculosis associations. They are the workers who unhallowed and unsung made, and though battered by the winds of adversity are continuing to make, this, the tuberculosis movement, a winning fight against disease.—

—*Hoosier Health Herald*, Indianapolis, Dec., 1932.

Health Education in the Philippines—An extensive plan for adult education has been announced by an Advisory Committee appointed by the Governor-General, a member of which is Dr. Jose P. Bantug, chief, Division of Public Health Education and Publicity, Bureau of Health, Manila.

Among the 21 topics suggested for lectures are the following on health: Intestinal parasites, Beriberi and balanced diet, Tuberculosis, Malaria, Infant and child care, Home Sanitation. Skin diseases.

Technical lectures on health to be delivered by insular, provincial, or municipal health officers or school Red Cross, or Puericulture Center nurses, or local doctors.

Read "The Health Talk" If You Talk About Health—Or if you get others to make health talks, you will wish to read "The Health Talk," by Iago Galdston, M.D. If you are chairman of a program committee, or leader or executive of any group which invites the presence of speakers on health topics you will want to read this pamphlet. But it will cause a lot of trouble for some people: you will know so much

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Ewart G. Roubabin, 130 East 22d St., New York, N. Y.

that will be necessary hereafter to make satisfactory health talks for your audiences. And why have a health talk, or why give one, unless it includes a reasonable proportion of the elements of a good health talk?

Here are the chapter headings: "The Nature of the Problem and the Fundamental Technique of the Health Talk"; "Curiosity, Its Application and Utility"; "Enlisting Interest"; "Imparting Information"; "Mechanics of Delivery"; "Leading to Action"; "On the Air"; "The Health Speakers Bureau"; "The Audience and the Speaker"; "Adjuncts of the Health Talk"; "Giving the Health Talk a Fitting Name." We cannot imagine anyone who talks on health who would not benefit through reading "The Health Talk." And this is one of a very small group of publications that we believe every public and private health agency should possess. Published by National Tuberculosis Association, 450 7th Ave., New York. 76 pp. 50 cents.

Fewer Words Will Do the Job— The address for purchasing most United States Government publications is "Superintendent of Documents, Washington, D. C." To add "Government Printing Office" merely cumbers the address. The G. P. O. is merely the printing office which prints the publications; the S. of D. is the selling agent.

Neither of the two should be given *for free publications*. Requests for *free publications* should go to the issuing department or other office.

Incidentally, there is now no "Bureau of Education"; it is called the "Office of Education," although the earlier title still appears on publications which have not been reprinted recently.

The Discussion Leader—Confusion as to the actual functions of a "discussion leader" was revealed at the an-

nual fall program session of the National Conference of Social Work. In this October meeting 50 to 60 leaders in social work gave half the day to consideration of reports by "observers" of the sessions at Philadelphia last June.

It was shown that often the so-called "discussion leader" was either a "commentator" on the previous address, or was an "opener" or "starter" of discussion. It was agreed that a "discussion leader" should actually "lead" or conduct audience participation, and that he should not be a speaker.

It was expected that hereafter the following quotation from the new Handbook for Chairmen of Divisions should be the ideal:

A Discussion Leader for purposes of definition is a person selected to preside during a discussion that is of a more informal character, to keep the discussion related to the subject, to stimulate thinking, and to act as a Discussant himself. This requires considerable ability and facility in handling a meeting and is an entirely different function from that of commenting on a particular paper. A Discussion Leader should be able to think quickly, cheerfully and graciously to shut off a person speaking extemporaneously from the floor on matters entirely irrelevant to the subject, to be at all times in control of the situation, and to be able from time to time to bring out the main lines of discussion or the points being made or to sum up the question at issue clearly for the benefit of the audience. Here again, careful preparation should be made.

The Discussion Leader should be advised in advance as to the purpose of the meeting and what it is hoped to bring out during the discussion. If possible, he should have access to the papers in advance of the Conference and should be permitted to make such arrangements with other individuals for participating in the discussion as he sees fit. The Division Chairman may act as the Discussion Leader but he usually has other responsibilities that prevent his careful preparation for discussion leadership. Unless the Division Chairman or Presiding Officer happens to be exceptionally skillful in leading discussion, it is wiser to select someone else as Discussion Leader (The Chairman is then free for the details of meeting management.)

In this case the distinction between the Discussant and the Discussion Leader should be clearly made to the person selected and at the appropriate time he should be presented to the audience and allowed to have full charge of that part of the meeting at his disposal.

Public Health in "Literary Digest"—There is always the possibility that your better publications may contain material which would appeal to the editor of *Literary Digest*. Selected reports of studies, annual reports, and other publications may be addressed to Arthur E. Bostwick, Science Editor of *Literary Digest*, Park Plaza Hotel, St. Louis, Mo. Please indicate especially interesting or significant pages.

One Hundred New Names—An editorial in the *Journal* (Dec., 1932) calls attention to the significant fact that on the Washington program of the A.P.H.A. "upwards of 100 new names were included as giving papers."

This is testimony to the wisdom and the energy of the various program chairmen. The easy way—repeating the same speakers year after year—is not the way of growth and progress.

RADIO

A successful radio talk service is maintained by the American Child Health Association, 450 7th Ave., New York. Once a month a talk is sent to 170 stations which have indicated a desire to receive the talks. Interested health agencies might check with A.C.H.A. as to use made of these talks by stations in their territory. *Copy free*.

Copies of a series of radio talks on mouth hygiene will be sent upon request to New York Department of Health, 139 Centre St., New York.

Radio talks from Illinois State Department of Health, Springfield: "Health Problems of Later Life," "Keeping Well Between 45 and 65,"

"Prime of Life and Its Health Problems," "Health Hazards of Adolescence and Early Maturity," "Sick Headache, Asthma and Hay Fever Victims," "The Healthiest Period of Life."

COÖPERATING GROUPS

The Massachusetts Society For Mental Hygiene, 3 Joy St., Boston, held a 3-day course on mental hygiene for Massachusetts girl scout leaders.

The Health Section of the Albany, N. Y., Council of Social Agencies has arranged a series of talks on "What The Social Worker Should Know About Disease."

"Health And Its Maintenance" is a reading list: "The Public Library Offers You These Books," says *Brookline Health Bulletin*, Brookline, Mass., Board of Health., Dec., 1932. *Sample free*.

NEW

High School Health Bulletin and *Child Health Study* are now issued in addition to *School Health Bulletin*, by Illinois Tuberculosis Assn., Springfield. All are attractively mimeographed on clear white paper of 20 lb. weight.

HONORABLE MENTION

To Illinois Tuberculosis Association: for giving date, number of pages, price, and address of publisher for all books offered as reading references in bulletins sent to schools.

HOUSE ORGANS

Of special interest to studious public health workers is the *Quarterly Bulletin*, Milbank Memorial Fund, 40 Wall St., New York. Better ask for a copy to sample its contents before seeking a place on its mailing list. The full-page photographs which "bleed" over the edges are more useful through a new device. An eighth of an inch blank band across the bottom of the page allows for a caption in 6 point type, without making the words obtrusive.

"That Annual Meeting," in *News Letter*, Victorian Order of Nurses For Canada, Ottawa (Jan., 1933), gives a baker's dozen of hints for making the meeting "different" and useful. Here is one idea:

Have a pioneer dinner, an occasion for bringing to the meeting, if possible, persons who shared in the beginnings of the organization and who have since gained distinction elsewhere. For such a dinner a supposed director of the organization in 1950 might talk about the old days of 1932 and the years which followed in a way to bring out the hopes and plans of the organization's future.

Pittsburgh's Health, Dept. of Public Health (Nov., 1932), had a "lamb and lion" cartoon on the common cold, and *Health Briefs*, Tennessee Dept. of Public Health (Nov. 15, 1932), reproduced a newspaper cartoon on "False Economy—Closing the Spigot and Opening the Bung!"

Four milk bottles on a door-step appear on the cover of *Bulletin*, State Board of Health, Louisville, Ky. (Oct., 1932). "Milk For Health." Inside several pages are given to "Louisville's Educational Milk Program."

Birmingham's Health, in its effective printed form, has been making good use of photographic covers, including an airplane view of the city, a group of laboratory utensils, and a three-dimension bar diagram of the falling death rate.

The Michigan Nurse, Lansing, has been re-born in appearance; an effective double-page spread of personality photographs.

New bulletins or house organs are reported for several health departments in California: Kern County, San Bernardino County, Fresno County, Alameda County.

Previously, monthly or bi-monthly

bulletins were issued by San Joaquin, San Luis Obispo, Santa Barbara, Imperial, and Los Angeles counties; and the cities of Los Angeles, San Diego, Sacramento, San Jose, Pasadena, and Oakland.

Corrections and Amplifications—

First, as to Jan., 1933, issue: "What Is Health Education?"—It should be spelled "Anette M. Phelan." "Timely Topics"—Price of single copies of *Canadian Public Health Journal* is 35 cents.

Corrections of material in Feb., 1933, issue:

"Honorable Mention"—The New York State Department of Health report lacked a complete index because of the sickness of the capable indexer of the department.

"Reporting" . . . Single copies of the 9-page review of 1932 by Commissioner of Health Shirley W. Wynne, New York City, will be sent on request.

Health Education in Boston—Ruth I. Parsons and C. E. Turner made a study of school and out of school health education during the school year of 1931–1932. The first of a 3-part report appeared in *New England Journal of Medicine*, 8 The Fenway, Boston. Jan. 5, 1933. 25 cents. This first part includes a more detailed review of activities, agency by agency, than ever we have seen heretofore.

The aims of this survey have been threefold:

1. To determine what agencies are carrying on Health Education in the city.
2. To determine the quantity, quality and adequacy of the work which each is doing.
3. To suggest ways of strengthening the present program of Health Education.

BOOKS AND REPORTS

Men Against Death—*By Paul de Kruif. New York: Harcourt, Brace, 1932. 363 pp. Price, \$3.50.*

The author has given us another series of biographical sketches of those who have become famous in conquering disease and in saving life. The book opens with a prologue which is something of an essay on prolongation of life, with various philosophical ideas sketched in. In it many well known biologists and others are mentioned. He takes a dig at periodical medical examinations, though confessing that he bows to the figures of eminent actuaries who show that they prolong life.

Beyond this, the volume is divided into 4 books. The men considered in the first book seem to have been selected more or less at random. There is a reason for classing together the three found in each of the remaining books, which have appropriate titles. With the exception of Semmelweis, Shaudinn and Finsen, who have been dead for years, the author knows personally all those of whom he has written and has gotten most of his material first-hand, though he has studied the literature as well.

The selections seem well made. Those whose histories are given have not only accomplished well worthwhile things, but have dealt with diseases which are widespread and of practical daily interest to all. The book is written in the well known style of the author. He goes into considerable detail, and apparently has the power of discerning the inmost thoughts and motives of those concerning whom he writes. Whether we like this particular style or not, there is no doubt that de Kruif appeals to the public, and his books have caused many laymen to look into the sciences in

which "men against death" have been laboring for so many years, oftentimes at great disadvantage, with little thought except the scientific aspects of the subject, and almost all of them on salaries woefully inadequate, especially when compared to the earnings of those in private practice of medicine, or in many lines of business.

The book is beautifully printed and illustrated, and deserves a wide circulation which we are sure it will have.

MAZÛCK P. RAVENEL

The Sanitation of Water Supplies—*By Murray P. Horwood, Ph.D. Springfield, Ill.: Thomas, 1932. 181 pp. Price, \$3.00.*

This volume is intended for students in municipal sanitation and public health. It deals with engineering, laboratory and public health aspects of water supplies. The author traces the development of sanitary water supplies from their beginning to the present time. The same interesting method is used in describing the specific phases of water sanitation. The sources, uses, consumption, and the requirements of a potable supply are discussed. Other chapters deal with the relation of water to disease, the purification and improvement of water supplies, water softening, sand filtration, and disinfection. Adequate examples are given to support statements concerning problems related to the production of potable water. Errors are almost absent. On page 93, however, a reversal of the terms pH 4.0 and pH 8.0 has occurred, which might be confusing to some readers.

The book is extremely well illustrated, and its composition is of the same high type for which the publisher is well known. NEWELL R. ZIEGLER

Streptococci in Relation to Man in Health and Disease—By *Anna W. Williams, M.D.* Baltimore: *Williams & Wilkins*, 1932. 260 pp. Price, \$5.00.

An introduction by Park emphasizes the need of a concise presentation of "the important facts and surmises connected with streptococci in health and disease." In the 220 pages comprising the monograph, Dr. Williams has crowded an orderly survey of enormous literature, the results of personal experimentation, and other information regarding streptococci (genus *Streptococcus* according to Bergey) which evokes admiration and promises practical use.

A plan suggestive of bacteriological textbooks is followed, with the early chapters given over to historical sketches, general classification of streptococci, and methods—properly evaluated—of cultivation and identification. Then follows generalized information as to the incidence of these organisms and their rôle in health and in local and general infections of man.

The latter half of the book is made up of chapters dealing with the relationship of streptococci to specific diseases—erysipelas, scarlet fever, septic sore throat, rheumatic conditions, and to various infections in the etiology of which a virus is more or less accepted. Photographs and tables are included, and an extensive bibliography completes the book.

It is essentially a usable book, a compact summary of practical knowledge, and the material is presented in such an easy reading style that it will serve for both immature and mature students. It should stimulate all to further studies.

The statement that the book is published by The Williams & Wilkins Company is sufficient recommendation of the quality of printing and binding.

ANNA DEAN DULANEY

The Youngest of the Family: His Care and Training—By *Joseph Garland, M.D.* Cambridge: *Harvard University Press*, 1932. 196 pp. Price, \$2.00.

This is another book on the care and feeding of the infant and young child. It has several merits not found in a number of other manuals on this subject. In the first place the material has been brought up to date and due consideration has been given to the mental hygiene of the child as well as to its immediate physical requirements. The chapter on the Runabout Age, while short, gives a good outline of the measures which may be applied to the preschool child.

The book is written apparently for the more intelligent group of mothers. It is conveniently arranged for reference. The line drawings and half-tone illustrations are excellent.

RICHARD A. BOLT

Syllabus of Medical History—By *Victor Robinson, M.D.* New York: *Froben Press, Inc.*, 1933. 110 pp. Price, \$1.00.

According to the definition of the term syllabus, an author presumably has a certain right to selection of topics, but when the selection is poor, one has the right to criticise. This book is said to consist of specimen questions and answers from the author's course, a specimen essay taken from a work of his, and a specimen chronology of goiter. Fifty pages are given to questions and answers, and 16 to the essay, the rest of the book being taken up almost entirely with reproductions of instruments, injuries to bone, etc.

We find that men like Loeffler, Bretonneau, and Lister are mentioned only incidentally, with no description of their accomplishments. The index does not even list diphtheria, typhoid fever, malaria, meningitis, and other important diseases, the study of which

has played a large part in the development of our present knowledge of medicine. All that we are told of anthrax is that Koch wrote a paper on its etiology. Loeffler's accomplishments are limited to the statement that he wrote with Koch on disinfection. Malaria, with its interesting and valuable history, is mentioned only in connection with the treatment of syphilis. Ross, Negri, Laveran, Budd, Gerhard, Banting, and many others who have made really great discoveries, are not even mentioned. The reviewer wonders how such a book ever came into being, and how it came to be published. A real syllabus of medical history would be extremely valuable.

It would be hard, of course, to write 60 pages without including some interesting facts, but there is so little told, even about those mentioned, and there are such flagrant omissions, that one cannot recommend the book for students or teachers, for whom the author says it is designed. Nearly two pages at the beginning of the book are given to some excellent quotations.

MAZYCK P. RAVENEL

pH and Its Practical Applications.

A New Handbook and Reference Work—By Frank L. La Motte, William R. Kenney, and Allen B. Reed. Baltimore: Williams & Wilkins, 1932. 262 pp. Price, \$3.50.

This little volume is essentially a discursive handbook. The first part describes the determination of pH by means of indicators, while the second part sketches the pH control practice in a number of industries. Chapters, in the latter part, are given to such subjects as water supply, water corrosion problems, disposal of sewage and industrial waste, sugar industry, gelatin and glue, leather, textiles, pulp and paper, food industries, cleaning, metal electrodeposition, soils, and microbiology. In many cases interesting charts are given

showing the pH zones optimal for various steps in the process under consideration.

The first section of the book would seem a bit one-sided, as the entire explicit mention of electrometric methods of pH determination is confined to about one paragraph, even though one such method, the hydrogen electrode potential, is treated as the basic method. The excuse given for such treatment is that "all electrometric methods require considerable experience and skill on the part of the operator." Even if such be the case, which seems questionable to the reviewer, the book would not have been enlarged much, and would seem more balanced, had there been a chapter included outlining the technic and the limitations of potential measurements.

Simplicity of presentation is the avowed aim of the authors and nothing could be desired in this respect. Indeed it may well be that many, lacking adequate technical training yet finding themselves in a position where pH control is essential, will find the book valuable as a practical guide.

ALLEN E. STEARN

Bacteriology for Nurses—By Mary Elizabeth Morse, A.B., M.D. and Martin Frobisher, Jr., S.B., Sc.D. 4th ed. Philadelphia: Saunders, 1932. 409 pp. Price, \$2.50.

This is a good book, composed of 30 chapters, 3 appendices and an index. Eleven chapters comprise the first section and are devoted to general bacteriology; the remaining 19 chapters concern special bacteriology and pathogenic protozoa.

The authors say they have practically rewritten the book to bring it up to date. Much new material on immunity, allergy, disinfectants, ultramicroscopic viruses, filterable forms of bacteria, dissociation, yeasts and molds, anaerobes and anaerobic technic, undulant fever,

and tuberculosis has been added, with illustrations. The arrangement has been made to conform with the demands of the standard curriculum.

The bulk of the book is on fundamentals, the appendices on methods. These have been reduced to the minimum to conserve space for the text proper. It is expected that an instructor will demonstrate or teach methods and the student take full notes, thus avoiding the necessity of detailed descriptions in the text. C. F. ADAMS

Bacteriology for Nurses. With a Laboratory Manual—By Royal M. Calder, M.D. Philadelphia: Saunders, 1932. 285 pp. Price, \$2.00.

A new textbook written distinctly for nurses—"with the *nursing application* of every bit of information strongly emphasized." Bold type is freely used to call attention to various headings, especially where special care and technic is needed.

Part I consists of 12 chapters that deal with the principles and practice of bacteriology and immunology, such as methods of study, infection and resistance, transmission and disinfection, diseases transmitted through discharges of the nose, mouth and gastrointestinal tract, wound infections, prevention of blindness, food poisoning, venereal diseases, insect-borne diseases and higher bacteria, yeasts and molds.

Part II consists of 9 laboratory exercises covering general methods for the study of pathogenic organisms and the bacteriology of water and milk. Following a few useful illustrations of the handling of simple apparatus, these laboratory exercises are furnished with blank lines and circles for notes and drawings.

The appendix consists of 20 pages of miscellaneous material of apt application, some of it concerning general or fundamental matters, and some referring to specific things, all very useful.

C. F. ADAMS

The Expectant Mother's Handbook—By Frederick C. Irving, M.D. Boston: Houghton Mifflin, 1932. 203 pp. Price, \$1.75.

This compact little handbook from the pen of an experienced obstetrician is well written, full of common sense, and attractively arranged. It explains clearly and without verbosity the anatomical, physiological, and hygienic aspects of pregnancy; touches on some of its dangers and complications; and gives what the patient wants to know about labor and the lying-in period. A rather unusual feature of the book is a chapter on the biological aspects of pregnancy.

This can hardly be said to be a simple enough book for all prospective mothers but the intelligent and well informed woman will find here everything she needs to supplement what she gets from her family physician.

MERRILL E. CHAMPION

Applied Bacteriology—By Thurman B. Rice, A.M., M.D. New York: Macmillan, 1932. Price, \$2.50.

The title of this book is misleading, as it is intended for nurses. The author disapproves of all existing texts on bacteriology for nurses on the ground that they are merely medical books "written down."

We regard this volume as excellent for its announced purpose. It contains a large number of illustrations, some good and instructive, and some poor. It is stated that they are "overdrawn" for the purposes of presenting a clear picture. The text is readable, and as far as we have been able to detect, accurate. We approve of the announced object of avoiding theory and stressing points necessary for diagnosis, the collection of specimens, and nursing treatment. As is well known to many of our readers, the author has a distinctly original and practical way of presenting his material, which is carried out in this latest work.

We can recommend it, but believe that nurses should have, in addition to lectures and a good textbook, practical laboratory experience, though the preface does not indicate that this is a text to accompany such practical training. The make-up and printing of the book are excellent. MAZYCK P. RAVENEL

Publications of the National Quarantine Service, Republic of China
—Series I—By Dr. Wu Lien-Teh.

This publication reviews the cholera situation in China, giving a very complete history of this disease in Shanghai, starting from the year 1820, when the modern history of cholera in China is considered to begin, up to and including the year 1929, and more especially portrays the great improvement in the cholera situation since the establishment of the National Quarantine Service on July 1, 1930.

For many years the problem of cholera in Shanghai has been an acute one but coöperation of the three health authorities in Shanghai (International Settlement, French Concession, and Greater Shanghai) was not achieved for the common purpose of combating this disease and improving health conditions in the community.

The establishment of the Ministry of Health in Nanking in 1928 was followed by the adoption of a new progressive policy, and in 1930 there was created a Central Cholera Bureau where the efforts of the three health authorities could be coördinated, all under the general direction of the National Quarantine Service, of which Dr. Wu Lien-Teh is Director. A program of anti-cholera vaccination was mapped out and an intensive epidemiological study of local cholera foci was undertaken, including examinations for carriers, possibility of water infection, etc.

When in the summer of 1930 an outbreak of cholera occurred, the authori-

ties were united and prepared to fight it, with the result that only 128 cases were recorded with 16 deaths. When compared with previous outbreaks of cholera in Shanghai, the 1930 outbreak showed not only a decided reduction in the number of cases and deaths but the onset of the epidemic occurred later than in many of the previous years. From May to September 537,034 anti-cholera vaccinations were performed. There is little doubt but that the strenuous anti-cholera campaign conducted earlier in that year contributed not a little to this satisfactory result. During the outbreak laboratory research was carried on regarding the recognition, viability, agglutination, etc., of the cholera and related organisms, the results of which are summarized.

The publication also includes an extensive report of a survey of the needs for establishment of adequate quarantine service for the port of Shanghai made by Dr. C. L. Park of Melbourne, Australia, Chief of the Epidemiological Division of the Health Section of the League of Nations, and Director of the Australian Quarantine Service.

F. A. CARMELIA

Medical Care for the American People—*The Final Report of the Committee on the Costs of Medical Care. Chicago: University of Chicago Press, 1932. Price, \$1.50.*

This volume is the result of 5 years of work and the expenditure of something like a million dollars contributed by a number of foundations. Assistance in the shape of supplementary studies has been given by a number of scientific organizations, and credit is given to state and local departments of health and other organizations for coöperation in field work. In addition to this final report, some 26 studies have been already published. The committee believes that a number of questions have been raised which need further

attention, and for several of them; outlines of studies have been made.

The report is divided into two chief parts; the majority and minority recommendations. In addition to the principal minority report, there is a second, by two dentists, and the volume is closed by two personal statements by members of the committee, one of which contains much food for thought, and the last, a statement that the recommendations do not deal adequately with the fundamental economical question, to study and consider which, the committee was primarily formed.

The majority report recommends that medical service, both preventive and therapeutic, "should be furnished largely by organized groups of physicians, dentists, nurses, pharmacists, and other associated personnel," and that these should be organized around hospitals. High standards are insisted on. It further recommends "the extension of all basic public health services," so that they will be available to the entire population, according to its needs. This requires greater financial support for health departments and full-time trained health officers and staffs. ". . . The costs of medical care should be placed on the group payment basis through insurance, taxation, or both methods," but medical services on the individual fee basis may be continued for those who prefer it. The committee recommends also that the "study, evaluation, and coördination of medical service be considered important functions for every state and local community," and that "the coördination of rural with urban services should receive special attention." The last recommendation deals chiefly with the training of physicians, dentists, pharmacists, nurses, nurse-midwives, etc.

The principal minority report recommends that "government competition in the practice of medicine be discontinued and that its activities be re-

stricted (a) to the care of the indigent and of those patients with diseases which can be cared for only in governmental institutions; (b) to the promotion of public health; (c) to the support of the medical departments of the Army and Navy, Coast and Geodetic Survey, and other government services which cannot because of their nature or location be served by the general medical profession; and (d) to the care of veterans suffering from bona fide service-connected disabilities and diseases, except in the case of tuberculosis and nervous and mental disease." The minority believes that government care should be extended to indigents in order to relieve the medical profession of the burden it now carries in this respect. It agrees with the majority in believing that "the study, evaluation, coördination of medical service be considered important functions for every state and local community." It recommends that "united attempts be made to restore the general practitioner to the central place in medical practice." It opposes vigorously the "corporate practice of medicine, financed through intermediary agencies," regarding it as being economically wasteful, unfair to the medical profession, and inimical to continued high standards. It believes that methods which can be fitted into present institutions and agencies without interfering with the fundamentals of medical practice be tried, and ends by recommending the development by state or county medical societies of plans for medical care.

From this abstract of the two chief reports, it will be seen that while there is agreement on some points, there is absolute disagreement on important fundamentals.

We recognize the inadequacy of this review, but the report itself is so succinct, and covers so many points, that a detailed review is impossible. The committee has been thorough in its

work and has considered almost every point that might be raised. Everyone recognizes that economic conditions have brought about a change in the relationship between the doctor and the people. Group practice has probably come to stay. Expenses have mounted so that it has been said only two classes of people in America get proper medical care—the poor and the rich.

The American Public Health Association is not primarily interested in the practice of medicine, although it is generally recognized by the members that efficient medical care plays a great part in promoting public health, by the early detection of cases, proper isolation, and the destruction of foci of infection. That it recognizes the difficulties of the present situation is proved by the many studies which have been carried on through grants for some years, but so far, it has not officially committed itself to one or the other of the reports of this committee. Until such a time, we can only commend the report to the careful consideration of those who are interested in adequate medical care and the many problems which are involved in extending it to all. The majority report as well as the several minority ones present questions which may well be considered by every thoughtful individual.

MAZYCK P. RAVENEL

Fads and Quackery in Healing—

By Morris Fishbein, M.D. New York: Covici-Friede, 1932. 384 pp. Price, \$3.50.

The craft of healing always has been a reasonably honorable one. Long before medicine emerged as a science, however, it was invaded by a host of mountebanks and imposters. Today it is infested with quacks and charlatans, with fakirs and faddists, mostly on the fringes of regular medicine, but not entirely so, for it is rumored that not all the shysters and incompetents are outside of the profession.

To this ilk the militant editor of the *Journal of the American Medical Association* and of *Hygieia* pays his respects with much gusto, and exposes to ridicule with his pungent pen the actual or alleged foibles of homeopathy, eclecticism, osteopathy, chiropractic, Christian Science, physical culture, and the various offshoots, imitations, and modifications of these dubious benefactors of mankind.

Other topics dealt with in a vigorous and frequently vitriolic manner are the methods of the late Albert Abrams; the antivivisectionists, the less ethical beauty culturists, and the more deluded of the psychoanalysts. Rejuvenation, birth control, food fads, physical therapy of the coarser sort, medical errors in newspapers, and medical advertising also come in for some scathing comments.

One anomalous chapter is devoted to fads in health legislation. This material, reprinted from a magazine article of some years ago and bolstered with diatribes on the federal maternity and infancy law and the care of veterans, is the weakest part of the book, so weak, in fact, that it totters. A final chapter on the choice of a physician consists mainly of a catalogue of the *Principles of Medical Ethics*. If this chapter had been omitted, not much would have been lost, especially since the highly diverting chapters on the various quacks emphasize clearly enough that abstinence from these forms of healing is wise. The pecuniary emoluments accruing to some of these imposters are, however, so attractively set forth that some readers may be inspired to go into such lucrative business.

This book is entertaining and instructive. It is well printed and deserves wide perusal. The layman could benefit much from the information contained in it, but it is doubtful if even such a persuasive volume as this will have any permanent effect in reducing

medical quackery. The privilege of being duped is one of the indefeasible rights of the American people.

JAMES A. TOBEY

History of Chinese Medicine—By K. Chimin Wong, Licentiate of Medicine and Surgery, Hongkong, Formerly Lecturer on Medical History, - National Central University, etc., and Wu Lien-Teh, M.A., M.D., Dr.M.Sc., Director and Chief Medical Officer, Manchurian Plague Prevention Service; Director, National Quarantine Service, etc. Tientsin, China: The Tientsin Press, Ltd., 1932. Price, \$7.50.

This monumental work was conceived of more than 15 years ago, and the actual writing has consumed some 10 years. One can readily understand this even by a glance through its pages.

The volume is divided into 2 books. The first, written by Dr. K. Chimin Wong, covers (1) The Ancient or Legendary Period, 2697–1122 B.C., (2) The Historical or Golden Period, 1121 B.C.–960 A.D., and (3) The Mediaeval or Controversial Period, 961–1800 A.D. The second book, running from 1801 to 1832, which takes up a little more than three-fourths of the volume, was written by Dr. Wu Lien-Teh, whose industry in connection with the Manchurian Plague Prevention Service, the National Quarantine Service, and other notable endeavors is well known.

The authors recognize that in the early period there were countless myths and legends recorded which are of interest chiefly to students of mythology. Later, these stories became more authentic, and the historical period gradually developed, which covered nearly 2000 years, extending over 3 dynasties. Medicine was practically dominated by philosophical teachers. The Han dynasty (B.C. 206–A.D. 220) of this period is memorable because of

the fact that during it, 3 of the greatest physicians produced by China lived, and is considered the most glorious period of Chinese medical history. These men laid stress on direct observation and placed medicine on a more scientific basis. From the 11th to the 17th centuries, there came a marked change in medical thought, which gradually developed into 4 schools. There were constant attacks both on the old and the new. Specialism was noticeable, and many important monographs were produced. The most notable feature of this epoch was the struggle between the old and the new forces, but the latter steadily gained ground. While there was a great deal of mysticism and superstition, many observations were made in anatomy, physiology, and therapeutics. Indeed, it seems that the Chinese discovered, in part at least, the circulation of the blood 2000 years before Harvey. The Nei Ching says: "All the blood is under the control of the heart." "The heart regulates all the blood in the body." "The blood current flows in a continuous circle and never stops." There was no distinction made between the arteries and the veins. The systemic and the pulmonary circulation were not differentiated, and weird functions were attributed to various organs.

During the T'ang dynasty (619–907 A.D.) Buddhism came into China, and with it, ideas of Indian medicine. Also the Taoist became active and a system of charms for the cure of disease was invented. The author of Book One designates the Chou dynasty as the "age of philosophy, the Han dynasty the age of science, the T'ang dynasty the age of superstition."

Book Two gives a short discussion of conditions prior to 1600 A.D., and describes the early contacts between China and western medicine, the influence of Buddhism, and finally the arrival of a foreign medical man in 738 A.D. The

author tells us that there were European physicians on the staff of the Mongol conquerors, describes the activities of the Nestorian Christians, the first Catholic missionaries, and the early Portuguese hospitals at Macao. It was during the reign of Wu Ti (B.C. 140-87) that the Chinese Empire extended its domain westward and brought about the early Euro-Asiatic contacts. This ruler was considered the greatest of the Han sovereigns. Knowledge of this period is due largely to the great historian of the Han dynasty, Szu-ma Ch'ien (B.C. 145-74). The author gives full credit to European medicine and to missionaries, among the first whom were the Roman Catholics (1294 A.D.) and attributes the developments in the 17th and 18th centuries largely to their influence. While they were not trained medical men, they had opportunities to demonstrate the value of western medicine, and introduced quinine. Western medicine was more firmly implanted by the surgeons of the East India Company and the first Protestant medical missionaries about 1820. For 50 years after, there was much effort by individuals, among whom Dr. Wu names Alexander Pearson, Senior Surgeon of the East India Company, who introduced vaccine against smallpox, T. R. Colledge, President of the Chinese Medical Missionary Society, Peter Parker, W. Lockhart, J. C. Hepburn, J. L. Maxwell, and Patrick Manson.

The modern conception of public health, as understood today, had its beginning after the outbreak of pneumonic plague in 1910, which swept Manchuria and cost 60,000 lives. American doctors played an important part during this epidemic.

It may be said that Book Two is largely a history of the missionaries, religious and medical, who have served in China, and the author is generous in the credit and praise he gives to them.

In 1911 came the beginnings of modern public health work under Chinese physicians, who since that time have maintained their leadership, many of them having been educated in Europe and America. A number of women have taken prominent parts in the new developments. There are many other interesting features which we would like to comment upon in some detail, such as the 2 outbreaks of plague in Canton and Hongkong, and Manchuria. In 1912, the Manchurian Plague Prevention Service under the direction of Dr. Wu Lien-Teh was established. A detailed account is given of the foundation of medical schools, described as "proper union medical schools," and the systematic training of nurses. The founding of the China Medical Board and its acquisition of the Union Medical College in Peking in 1915, was a most important step. Coincident with advances came the founding of Chinese medical journals, a list of which is given. Many standard books were translated into Chinese and published.

There are lists of persons, a summary of dynasties, geographical names in Chinese, with their English equivalents, chronological tables, and finally an excellent index. The volume is profusely and well illustrated, while charts, such as Figure I, which illustrate the chief sources of Chinese medicine, are of great help to the foreign reader.

One cannot but speak with the greatest admiration of the thoroughness with which the work has been done and the enormous amount of labor expended. Dr. Wu Lien-Teh believes that a new spirit has arisen in China among all classes which has brought about changes of relationship between the foreigners and the Chinese, so that missionary colleges, hospitals, etc., are ready to adjust themselves to Chinese views and to elect Chinese as presidents and directors, as well as to make many

Chinese appointments. China is ready to discard many of its old ways, to receive and adopt western ideas and new ways of living.

The English used by both authors is excellent, and we only wish that American writers could be as explicit and succinct as these learned foreigners have shown themselves to be. The printing and make-up are excellent. Altogether, the book is most useful and interesting, opening up to us the history of this great Empire, in which civilization flourished long before most of our western countries came into organized existence.

MAZYCK P. RAVENEL

The Curative Value of Light—By Edgar Mayer, M.D. *New York: Appleton, 1932. 175 pp. Price, \$1.50.*

In the January 16 number of *The Journal of the American Medical Association*, Dr. Mayer presented an article on the present status of light therapy which has been of great value to students of this form of therapeutics.

With the development of sun lamps, ultra-violet transmitting glasses, and the general urge from the sales viewpoint to greater purchase of these means for producing artificial sunlight, there has arisen in the lay-mind many problems.

Many of these problems are now resolved for the layman in this new book of Dr. Mayer's. In it he tells simply and clearly the things that the layman wants to know about what the elements do, what sort of disease conditions may be prevented by ultra-violet treatment, how much of the body should be exposed during sun bathing, how to use the lamp with children, etc. Answers to all of these questions are to be found in this new and valuable contribution to public health; and not the least of its values is advice as to

how to avoid over-dosage and ill-treatment.

The language is simple and clear and the book full of the things we all wish to know.

W. H. EDDY

Teaching Nutrition to Boys and Girls—By Mary Swartz Rose. *New York: Macmillan, 1932. 198 pp. Price, \$2.00.*

That proper diet selection will prevent ill health—is today accepted science. But how to make individuals practice such food selection?

Mrs. Rose, in her *Feeding the Family*, and *Foundations of Nutrition*, has already established her position as a successful organizer of what should be known and done in making food selection an aid to health. But in those books she addressed an adult audience.

In the present book she has evidenced an appreciation that if children can be made to realize what food does for them and to seek voluntarily those foods which produce bodily vigor and happiness, adult problems will be much simplified. It seems to me that her text not only shows realization of the advantages of beginning early with nutritional training, but also shows skill in making children learn by doing. Tests which she described would make the acquisition of essential facts about foods not only painless but enjoyable to the average child.

The form of the material presented also adapts itself readily to any elementary school curriculum, as the test described can be made a part of the child's general science experimentation and does not represent another course of study to be fitted into a crowded curriculum.

It seems to me that the book should be strongly recommended to the attention of all elementary and high school teachers.

W. H. EDDY

ASSOCIATION NEWS

Sixty-second Annual Meeting of the American Public Health Association, Indianapolis, Ind., October 9-12, 1933,
Headquarters, Claypool Hotel

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

- Dr. U. B. Bowden, Pelham, Tenn., County Health Officer
Franklin M. Foote, B.S., 330 Cedar St., New Haven Hospital, New Haven, Conn. (Student) (Assoc.)
Dr. G. W. Kirk, Shepardsville, Ky., County Health Officer
W. E. Noblin, New Court House, Jackson, Miss., Director, Hinds County Health Dept.
Edwin R. Van der Slice, M.D., 530 N. Butler, Lansing, Mich., (after May 1) Health Officer
Louis Van Hoesen, M.D., Prospect Ave., Hudson, N. Y., Health Commissioner, County of Columbia
Adolph Weinzirl, M.D., 3600 Harford Rd., Baltimore, Md., Epidemiologist, Health Dept.

Laboratory Section

- Robert M. Pike, Ph.D., Otsego County Laboratory, Cooperstown, N. Y., Bacteriologist

Public Health Engineering Section

- Nathan B. Jacobs, 507 Westinghouse Bldg., Pittsburgh, Pa., Consulting Engineer
Arthur Taylor, C.E., City Hall, Beverly Hills, Calif., Engr. Beverly Hills Water Dept.

Food and Nutrition Section

- Laura C. Pepper, Dairy Branch, Dept. of Agriculture, Ottawa, Ont., Canada, Lecturer, Milk Utilization Service
Roger W. Truesdail, Ph.D., 1206 Maple Ave., Los Angeles, Calif., Food and Nutrition Consultant

Industrial Hygiene Section

- Ben H. Grimes, Bessemer, Ala., Box 144, San. Inspector, Tenn. Coal, Iron & R. R. Co.

Public Health Education Section

- Raynor E. Anderson, Financial Center Bldg., Oakland, Calif., Secretary, Public Health Committee, Oakland Chamber of Commerce
Evangeline Moore Darrow, Dairymen's League Cooperative Assn., 11 W. 42 St., New York, N. Y., Assistant Director, Home and Health Education Departments
Dr. Luis Gaitan, Callejon Manchén No. 14, Guatemala City, C. A., Subdirector and Secretary of Public Health (Assoc.)
Gerry R. Holden, M.D., 1022 Park St., Jacksonville, Fla., President, Florida Medical Assn.

Public Health Nursing Section

- Virginia Atkinson, R.N., Van Lear, Ky., Public Health Nurse
Anne F. Beven, R.N., Battle Lake, Minn., Field Nurse, Ottertail County Sanatorium
Mary Keith Cauthorne, R.N., State Department of Health, Charleston, W. Va., State Advisory Nurse
Ruth Fisher, R.N., 105 E. 7th St., Plainfield, N. J., Director, Visiting Nurse Association
Grace Frauens, R.N., 54 E. 53 Terrace, Kansas City, Mo., Educational Director, Visiting Nurse Association
Clarissa Gibson, B.A., 4101 Walnut St., Philadelphia, Pa., Supervisor, Public Health Nursing Dept., Babies Hospital
Viera M. Tuhy, R.N., 663 N. Main St., Wilkes-Barre, Pa., Communicable Disease Nurse, City Health Department

Unaffiliated

- Agnes Gelinias, R.N., Mary McClellan Hospital, Cambridge, N. Y., Instructor of Nursing
June A. Ramsey, R.N., Harper Hospital, Detroit, Mich., Superintendent of Nurses

PUBLIC HEALTH ADMINISTRATION

Commonwealth Fund—Organized "to do something for the welfare of mankind," the Commonwealth Fund in 1931 aided rural health work in 4 southern counties, where departments were previously unbalanced and inadequate, to establish a level of consistent integrated service which should be stimulating to other communities. The development of traveling field units has spurred county health officers to better planning and increased achievement. In Massachusetts, two groups of towns have been helped to pool their resources in modern health units. Six rural hospitals were given assistance, and 36 clinical institutes have been supported. Forty-five physicians and dentists from small towns were sent to medical centers for postgraduate study, and 32 picked undergraduates in medical schools were given scholarships to prepare for rural practice. Three medical schools serving rural clienteles were enabled to teach preventive medicine more effectively. These are only some of the activities in the public health and medical fields which were aided in a constructive manner.

In its public health program, the Fund tries to strike a balance between sound general principles and the strategy which is dictated by the needs and psychology of a given community. One of the most effective tools for strengthening both plan and performance is the field unit which has been set up in each of the 3 states. This unit, an innovation in rural health organizations, consists of a team of carefully selected workers—a physician trained in public health, a nurse, a sanitarian, and a clerk. Singly and in combination, these workers act as intermediaries between the state health officer and the local health department, bringing the former accurate information and a skilled interpretation of local situations, advising the latter, stimulating better technic in individual tasks, and helping to map the strategy of local service.

Diphtheria Prevention Programs

—At a luncheon conference at the annual meeting of the American Public Health Association in Washington were presented mimeographed outlines of diphtheria prevention programs of various cities in the United States and Canada. Extracts from these reports may be of interest to public health administrators. In the 1931 campaign in Chicago, the formal drive for immunization began in October with intensive radio publicity of 10 days' duration, in which 54 talks over 9 local stations were given by members of the Board of Health staff, and daily bulletins issued by the board were read by station announcers at various times of the day.

One of the greatest helps that we have had was the announcement from the altars in all Catholic churches that on certain days preventive treatments would be given in the district parochial schools and all mothers with children over 6 months of age were urged to bring them in for these treatments. Arrangements to give these treatments in a particular parochial school were never made until a representative from the Chancery office had conferred with the priest, after which the nurse in that district conferred with the priest and the sister superior concerning the final arrangements. On the Sunday of the announcement, an attractive folder, containing a letter from the Archbishop and another from the president of the Board of Health, was handed out. Just before beginning the treatments in a public or parochial school that district was canvassed by the nurses and every mother invited to bring the preschool children in on the date set.

The prevailing note of this campaign was to protect the preschool child. Very little was said about the school child, though the usual procedure of immunization in the schools was continued. A total of 70,887 preschool children were given two injections of toxoid, 1 week apart, while 47,106 school children between 6 and 10 years of age were given three doses of toxin-antitoxin, 1 week apart.

In Baltimore, a 6-week period prior to the launching of the campaign on May 1, was allowed to elapse, during which time the department made every effort to "skim off the cream" of the diphtheria prevention practice and steer it into the offices of the private practitioner. During this period the department made available to practising physicians specially prepared literature for use in their offices in connection with diphtheria prevention. The time of the beginning of the campaign was thought to be especially appropriate since May 1 each year is nationally and locally proclaimed Child Health Day and is the time at which the parent interest of the city is most likely to be focused upon the health of its children.

The Mayor officially inaugurated the drive by issuing a special May Day proclamation. The Baltimore Association of Commerce gave every assistance to the Health Department in the campaign by supplying the names of industrial plants employing more than 50 persons, and by publishing articles in their monthly journal, and in this way bringing the drive to the attention of the leading business executives of the city. As a result of this, over 150 industrial plants placed approximately 49,000 circulars on diphtheria prevention in pay envelopes. About 74,000 diphtheria circulars were sent to their subscribers by the Chesapeake & Potomac Telephone Company. Over 100,000 pamphlets containing a message to parents about diphtheria were distributed to pupils of elementary schools in whose homes there were infants and children under school age. During Negro Health Week, which began April 3, 18 meetings were held and diphtheria prevention was stressed; 46 talks were given, approximately 18,000 parents reached, and about 15,000 diphtheria prevention pamphlets distributed.

Ministers coöperated by announcing to their congregations the opening of the drive. Motion picture houses of the city carried during the first week in May a special trailer giving a brief message on diphtheria prevention. It is estimated that this trailer was viewed by audiences numbering more than 500,000 individuals. Radio stations of the city assisted by giving short announcements at opportune times during the campaign. The daily newspapers gave generously of their space for editorials and feature stories following the

progress of the drive. In addition, special articles were published in the *Catholic Review*, *Jewish Times*, *Magazine of the Women's Civic League*, *Baltimore Association of Commerce Journal*, *Boy Scout Magazine*, and *Baltimore Health News*.

An impetus of inestimable value to the campaign was given by the Baltimore Department of Education and the Maryland Congress of Parent-Teachers. With the adoption of the Children's Charter of the White House Conference on Child Health and Protection as its program for the guidance of its activities for the present year, the Maryland Congress of Parent-Teachers has taken an active part in diphtheria prevention in the preschool age group. Health officers from the staff of the Baltimore Health Department spoke on the subject of diphtheria prevention at many of the Parent-Teachers meetings during the first part of the year. Their 15-minute talks were followed by a 5-minute talk by a parent who presented the plan of coöperation of the Maryland Congress with the Health Department.

In Vancouver, Wash., circulars are sent to the families of all school and preschool children. Personal contacts are made by members of the Parent-Teacher Associations. Toxoid is used for children up to 12 years of age, and toxin-antitoxin for older children. Some 12,899 children have been treated and it is estimated that about 85 per cent of preschool and school children are immunized.

... The year the immunization was started, there were 33 cases and 5 deaths from diphtheria. For the past 2 years there have been no cases and no deaths.

Milwaukee reported that in 1931 there were 13,038 immunizations conducted in schools and 11,284 in special clinics for preschool children with the coöperation of the county medical society, the Parent-Teacher Associations, and the American Legion Auxiliaries. Middletown, N. Y., reported that 90 per cent of children under 5 years and 96 per cent of those between 5 and 14 years have received immunization treatments. The system includes a definite follow-up in the homes of all infants

and preschool children by the public health nurse.

The success of control of diphtheria in Lethbridge, Alberta, Canada, is believed due to "the lack of any coercion and the cordial coöperation of all concerned." In 1922, with a population of 11,000, there were 87 cases of diphtheria, with 5 deaths. The last case of diphtheria was in 1929 in a family none of whom had been immunized.

In Hamilton, Ontario,

. . . We sell diphtheria immunization to our citizens in the same manner that commercial concerns sell goods. Our nurses and inspectors call and persuade. All baby clinics are centers for the immunization of preschool children; the schools for both school and preschool children.

In 1920, there were 596 cases, with 44 deaths; in 1931, there were 5 cases, with no deaths; and in 1932, no cases.

New Jersey—The district health officer plan is proving its worth on a state-wide basis in New Jersey according to the annual report of the State Department of Health for the year ending June 30, 1932. Such a plan has been carried out for a decade in Monmouth County and in a group of South Jersey counties. There are now 5 district health officers in the state. New Jersey was admitted to the original morbidity reporting area of the United States, having shown by its official records that the required standard of completeness had been reached. This area was developed under the auspices of the U. S. Public Health Service for the diseases of diphtheria, measles, scarlet fever, typhoid fever, and whooping cough. The plan is somewhat comparable to the registration area for births and deaths.

Courses in public health administration offered jointly by Rutgers College and the State Department of Health were attended by 37 students during the summer. Among them were 2 health officers, a physician, 15 sanitary

inspectors, 5 public health nurses, and 7 other officials. Eighteen members of an advanced class finished the two-summer course and received the certificate in public health from Rutgers. There have been 58 students who have finished the course since it was established in 1926.

New Zealand—One of the outstanding features of the year 1931–1932 was the establishment of a new low infant mortality record of 32 deaths per 1,000 live births. The first-month mortality appears to be falling here to a lower level, the rate in 1931 being 22.7 as compared with 25.8 in 1927. It is also gratifying to note a steady reduction in deaths due to puerperal fever from 56 in 1927 to 18 in 1931.

In addition to the public medical and surgical hospitals, which also admit to the general wards a few emergency maternity cases, cases of puerperal sepsis, and obstetrical cases requiring surgical intervention, there are 7 state-controlled maternity hospitals providing 121 beds, 75 public maternity hospitals or maternity annexes attached to public hospitals providing 508 beds, 282 private hospitals providing 852 maternity and 1,333 medical and surgical beds. Seventy-three of the maternity hospitals also admit a limited number of medical and surgical cases under strict regulations excluding or restricting the admission of septic surgical cases.

The outstanding need in regard to all public maternity hospitals is more extensive, more systematic, and a higher quality of antenatal care, particularly with regard to closer supervision by well qualified obstetricians.

Here, as in other localities, there is observed a rise in the death rate from septic abortion.

There can be no doubt that the majority of these cases are due to the practice of criminal abortion, the incentives to the practice of which are mainly social and economic. The economic factor is emphasized by the marked

rise in the number of deaths occurring since the year 1928. [Twenty-six out of 29 cases in 1931 occurred in married women.] The means of decreasing this dangerous method of limiting families can best be dealt with by societies concerned with the welfare of women. If the enormous risk to life caused by criminal abortion was appreciated by those concerned, it might cause some women at least to abandon that method of meeting a difficult situation.

School Health Service—The medical officer of health of Hamilton, Ontario, Dr. James Roberts, recently prepared a report on the amalgamation of health services which faces frankly many questions frequently raised and is worthy of study by health administrators. Extracts from this report follow.

In looking back over recent years of my experience as Medical Officer of Health, I find the discussion as to whether medical inspection of schools should be under the supervision of the Board of Health or Board of Education to have been of annual, nay, even of perennial interest. At times reasonable and dispassionate, the argument has occasionally waxed warm and even acrimonious.

Permit me at the outset of my remarks to call your attention to a fundamental consideration which has not been sufficiently emphasized in the presentation of our problem to those who are not nurses and doctors, but which is of paramount significance to a proper conception of what school hygiene, looked at from a broad and really worth while viewpoint, comprehends. We refer to the difference between "health supervision" and "instruction in health." The former, for the infant, preschool child, school child, adolescent, and adult is preëminently the duty of the official health department. The latter is the function of the educational authority. To except the school child arbitrarily from any comprehensive program of the Department of Health can be defended on no grounds nor by any process of sound reasoning. Health instruction is the business of the Board of Education. Health supervision and protection is the responsibility of the Board of Health and the Medical Officer of Health. . . .

Both academically and strategically the teacher is better equipped to carry on the teaching of health and hygiene in the school-room than the nurse. . . . Not only would I insist on the school authorities seeing that the teacher's training is adequate to insure that this type of instruction shall not be car-

ried out in a perfunctory or half-hearted manner, but that in all the educational curricula of the country the teaching of health and hygiene shall be so incorporated as to invest them with the importance which their influence on the future of our citizenship demands. . . .

Corrective physical education has become as indubitably and acceptedly a part of the school program as manual training, vocational guidance or domestic science or any other of the so-called fads which once upon a time aroused alike the criticism and the deprecation of the taxpayers. Corrective gymnastics, postural exercises, orthopedics, rest, nutritional clinics, sun baths, open air schools, etc., have become indispensable adjuncts in our efforts to insure the ability of the child to attend school and to make the most of his educational opportunities. In the evolution or reorganization of existing school health services, whether under the Medical Officer of Health or School Medical Officer as the case may be, these services are essentially medical as to their establishment and successful maintenance. . . .

The Medical Officer of Health takes the stand, logical and convincing to himself, no matter how irrational it may seem to others, that the necessary visits to the school in connection with the control of communicable diseases offer exceptional opportunities at the same time for search and investigation into the causes which later in life lay the foundation for physical and mental ill health, and that inasmuch as the schools have the children under observation for only 5 to 6 hours per day and for only 195 of the 365 days in the year, any program of health supervision undertaken by the school authorities must of necessity be partial, isolated and in most cases ill coördinated with the scheme of preventive medicine which is in operation throughout every day in the year, and which, moreover, is often responsible for some of the best and most intensive efforts of the Health Department during those months of the year when the school health service, no matter how urgent the necessity, has entirely ceased to function. It is obvious, therefore, and to every one, that where health work, even to the extent of overlapping the work of the Health Officer in the control of contagion is carried on, that official becomes legally responsible for any miscarriage or neglect of duty and must not only carry on a campaign against infections in the public schools but as is the case in this city at the present time, must organize and carry on a similar crusade in the private and parochial schools. . . .

We are, in fact, at the present time, and have been for some years past, in the anomalous position of providing a dental service for

both public and parochial schools, a nursing service for the control of communicable diseases in both classes of schools and a service for the correction of physical defects in the home, or, in other words are carrying on a generalized nursing service covering the entire area of the city. . . .

Just here it would seem opportune to say a few words setting forth the advantages of such a nursing service. Accompanying my report is submitted a map showing the nursing districts which after due regard to density of population and other details necessary to be considered would, in our judgment, be adequate to insure the successful working out of the proposed amalgamation. These districts are so arranged that the district nurse in each case may take care of all children, school and preschool in her area, not only with respect to her work in the schools, but will be able to assume responsibility for attendance at clinics and to follow up work in the homes. Contacts from contagious diseases and absentees from schools on account of presumptive contagion or other disabling causes can be visited without overlapping, as the district over which any particular nurse assumes health supervision contains all that portion of the city from which the attendance at school or schools is derived. . . .

That a system of generalized nursing is the ideal in the field of public health is the opinion of those who have made a comparison of both specialized and generalized systems and who are qualified to make a pronouncement. . . .

It cannot but appear self-evident to anyone who has made a study of our health administration as its outlook has expanded and its development has progressed by leaps and bounds during recent years, that we are not dealing here with merely an educational reform or a social problem, but with a world wide realization of the importance of preventive medicine in the conservation of life and health. For this reason it would seem patent for the Health Officer to undertake whatever measures are reasonably available to promote the health of the entire community at all times and for those of any age. He cannot without laying himself open to the charge of inconsistency assume responsibility for the health of children up to 5 years of age, then turn them over to another official until they are 16, and subsequently without adequate records in his possession concerning the events in their physical and mental career at school, be expected to take the necessary steps to insure for them a healthy manhood and womanhood. . . .

We all, whether health or school officials, doctors, nurses, or lay persons, take a con-

scious pride in the great child hygiene movement, the impulse of which has travelled round the world and the influence of which has been felt to a greater or less degree in every city, town, and hamlet to which the gospel of hygiene and sanitation has penetrated. We all fully realize that as never before in history the present is the era of the child, and that medical inspection of schools, no matter by what authority carried on, has made an outstanding contribution to the betterment of the status of our children. In the future, as in the past, no matter what may be the decision of the city's representatives on the proposed amalgamation, our desire will be to coöperate to the best of our ability with School Boards or other agencies engaged in health and social work, to the end that we may forget our personal differences and consider only the child. Only by the assumption of such an attitude can our efforts be successful and the children be assured of a square deal.

Middletown, Ohio — *The Story Without Words* is the title of the 1932 health department report of this city of 30,000 population. The general death rate was 8.3; the infant mortality rate 48. There were no deaths from diphtheria. Births and deaths are tabulated by wards, and rates are calculated for the city for each of the past 10 years. Cancer deaths are tabulated by organ or part affected. Nurses' visits numbered 12,844. By careful tabular arrangement, an enormous amount of pertinent information is given in this 2-page report.

Lincoln, Neb.—In the 1932 report of the health department, reference is made to the advantages of the housing of the department in the new municipal building, one-sixth of the space being given to that department. A new laboratory was equipped and saved the city \$1,200 per year on bacteria counts. A newly established diagnostic X-ray equipment is saving the city \$2,400 per year. A skin clinic and an arthritis clinic are proving useful. A council of health agencies has been formed with 14 participating agencies.

LABORATORY

PROPOSED CHANGES IN THE NEW (SIXTH) EDITION OF THE STANDARD METHODS OF MILK ANALYSIS

ROBERT S. BREED, PH.D., F.A.P.H.A.
New York Agricultural Experiment Station, Geneva, N. Y.

AT the Washington meeting of the Laboratory Section Dr. E. M. Bailey, Referee for the Chemical Section of this Report and Dr. R. S. Breed, Referee for the Bacteriological Section, presented manuscripts for the new edition of the *Standard Methods of Milk Analysis* to the Committee on Standard Methods. These were accepted by the committee for presentation to the Laboratory Section. Publication will be delayed for one year in order to permit study and criticism of the report by members of the Section and of other interested associations.

The Chemical Section of the Report, as in previous editions, represents the work of the Association of Official Agricultural Chemists, an association which coöperates with the American Public Health Association in issuing the *Standard Methods of Milk Analysis* report.

The chemical methods for the analysis of milk have been revised to conform to the latest revision of the official methods of the collaborating association. The scope of the section has been enlarged by the addition of methods for testing cream and ice cream. Methods for the determination of available chlorine in preparations used for sterilizing milk equipment and utensils have also been included. The list of selected references has been revised and enlarged.

There are various modifications of

the Babcock method being used at the present time for the determination of fat in ice cream. Some of these procedures have been studied by the Association of Official Agricultural Chemists but as yet no method of this type has been adopted by that body. This question is being further studied by the association named and if a satisfactory procedure is found and adopted by them it will be included in a later report.

The most important changes in the Bacteriological Section consist in dropping all reference to the Frost Little Plate technic and the Stewart-Slack procedure, both of which appear in the present edition as tentative or optional procedures. The description of these two methods has been omitted because of the fact that they have not found extensive use in official routine milk control work and because of a desire to bring about a greater uniformity in the procedures used.

Five new sections of this report have been drawn up to cover procedures already being followed in many milk control laboratories. These are presented as tentative methods and will be placed in an appendix to the main report.

The first of these sections deals with the detection of organisms of the *Escherichia-Acrobacter* group. The two media that are recommended are brilliant green lactose bile (2 per cent),

and Endo agar plates. Chief emphasis is placed on the use of this test on fresh (less than four hours old) or very high quality (less than 10,000 count) raw milk, as a means of determining the efficiency of pasteurization and as a means of detecting recontamination after pasteurization.

Tests for determining the sterility of milk bottles, cans, and other dairy utensils and tests for detecting the presence of thermophilic, psychophilic and saccharophilic bacteria are included. Throughout the report the position is maintained that the methods used should be sufficiently complete to detect the presence of bacteria that may not grow readily on standard agar plates incubated at 37° C. in the belief that high quality milk should not contain large numbers of living or dead bacteria of any type. In view of the importance of recognizing the difference between streptococci capable of producing septic sore throat epidemics and ordinary mastitis streptococci, a section is to be included giving the technic for determining the difference between these two groups of streptococci. At the request of the International Dairy and Milk Inspectors' Association, the Standard Methods Committee has also asked that a section be prepared dealing with

the technic to be used in determining the number of bacteria present in ice cream. Dr. F. W. Fabian has been appointed an Associate Referee to prepare this section of the report.

The sections discussing the standard agar plate technic, the microscopic method of counting bacteria, the methylene blue reduction technic and the sediment test have been completely rewritten and the material organized in a form similar to that used in the *Standard Methods of Water and Sewage Analysis*. The composition and reaction of the standard agar used for water, sewage and milk work has been made exactly the same in the two reports. All reference to beef infusion agar has been dropped out of the milk report. It is required that laboratories carry out certain verification procedures wherever punitive actions are to be based on the result of routine analysis. The cut showing standard sediment discs has been discontinued and it is recommended that laboratories purchase the photographic standards prepared by the Connecticut State Department of Health. About 50 copies of the preliminary manuscript of the bacteriological section of the milk report have been distributed to laboratories throughout the United States and Canada for their study and criticism.

VITAL STATISTICS

Health Conditions in New York State, 1932—Notwithstanding the continued economic depression, unprecedented in scope and intensity, the health of the people of the State of New York during the year 1932 has, in general, been most favorable.

The birth rate has dropped to a new low figure, 15.0 per 1,000 population, and the total number of births, less by 10,000 than in the previous year, has never been lower since the registration became practically complete. The gen-

eral death rate in the state, 11.3 per 1,000 population, was the lowest ever recorded. To realize the degree of improvement represented by such a low rate one need but recall that at the beginning of the century the annual number of deaths was 18 in 1,000. Had this rate prevailed last year, there would have been 90,000 more deaths than the number which actually occurred.

A new low rate was also recorded for the mortality of infants under 1 year of age. Out of every 1,000 babies born

alive, 53 died during the first year of life—less than half of the corresponding rate 20 years ago. Among the important diseases of children, new minimum points were reached by mortality from diphtheria, 2.1 per 100,000 population; whooping cough, 2.3; and diarrhea and enteritis, under 2 years, 6.4. The death rate from measles, 1.6, was lower only twice in the past. On the other hand, due to the greater prevalence of scarlet fever, the mortality from this cause, 2.8, has not been higher since 1922.

With the outstanding exceptions of suicide, with a rate of 20.2, and diabetes, 29.8, both the highest on record, and the continued high mortality from heart disease, 293.3, and the puerperal causes, 58.2 (per 10,000 total births), the death rates from most of the other important causes have either changed but slightly or dropped to new low levels. The downward trend of mortality from tuberculosis continued uninterrupted, the 1932 rate, 61.1, being the lowest ever known in the state. The pneumonia rate also established a new minimum of 96.6. For the first time in a quarter of a century there was a drop in the cancer death rate and although the reduction was only slight, any break in the rising mortality from this cause should be noted. The homicide rate, though still high (5.7), was somewhat below that in 1931 and the mortality from alcoholism, 5.7, was the lowest in 10 years.

Among the other favorable facts, attention should be called to the rate of fatal automobile accidents, 22.0, the lowest in 4 years, and that of other types of accidents, 47.0, which has never been lower. These figures reflect not only the effect of safety measures, but also of the decrease in the number of automobiles on the highways and machines in operation in factories.

Compared with 1931, cases of sickness from reportable diseases increased

by 15,000. More cases of scarlet fever were reported than ever before, the total of 40,000 being greater by 50 per cent than the corresponding figure in 1931. Cases of measles increased by 6,000, whooping cough, by 1,500. The number of reported cases of syphilis, almost 60,000, was by far the greatest on record, representing a rise of more than 100 per cent since 1925. Among the favorable events was the drop in cases of poliomyelitis, the total for the year, 333, being a gratifying contrast to the 6,000 or more cases registered during the epidemic of 1931. A new minimum point was reached by diphtheria, with 4,200 cases in the entire state as compared with 11,000 only 4 years ago.—*New York State Weekly Health News*, 10:25-26 (Feb. 13), 1933.

Birth and Death Experience in Illinois, 1932—Complete provisional statistics for 1932 give Illinois the lowest birth and death rates on record in the state. There were 83,183 deaths and 111,523 births reported, giving rates per 1,000 estimated population of 10.7 and 14.4, respectively. Previously the lowest corresponding rates were 10.9, the death rate in 1930, and 15.4, the birth rate in 1931. The number of births in 1932 was 7,265 short of the 1931 figure and 29,914 below the 1924 record, the year of highest birth registration. Since 1924 the number of births in Illinois has steadily declined, the downward trend being much more pronounced since 1929.

New all-time low death rates were recorded for measles with a rate of 0.7 per 100,000; diphtheria, 3.1; tuberculosis, 55.0; diarrhea and enteritis (under 2 years), 7.0; and infant mortality, with a rate of 52.0 per 1,000 live births reported. The death rate from typhoid fever, 1.6, was about on a par with the previous low, 1.5.

New all-time high death rates were established for heart disease with 235.0

deaths per 100,000 population against a previous high of 221.5; cancer, 116.0 against 112.6; diabetes, 26.7 against 25.7.

Automobile accidents resulted in 2,104 deaths, giving a rate of 27.1 per 100,000 as compared with 2,333 deaths and a rate of 28.7 in 1931.—*Birth and Death Experience in Illinois, 1932.*

Preliminary Report on Marriage and Divorce for Rhode Island, 1932—The Bureau of the Census announces that, according to the preliminary returns received, there were 4,080 marriages performed in Rhode Island during the year 1932, as compared with 4,635 in 1931, representing a decrease of 555 or 12 per cent. In 1922, there were 5,669 marriages performed.

During the year 1932 there were 730 divorces granted in the state, as compared with 674 in 1931, representing an increase of 56 or 8.3 per cent. In 1922, there were 819 divorces granted.

The estimated population of the State of Rhode Island on July 1, 1932, was 698,000, and on July 1, 1931, 694,000. On the basis of these estimates, the number of marriages per 1,000 of the population was 5.8 in 1932, as against 6.7 in 1931; and the number of divorces per 1,000 of the population was 1.05 in 1932, as against 0.97 in 1931.—*Preliminary Report on Marriage and Divorce for Rhode Island*, Dept. of Commerce, Bureau of the Census, 1932.

Diphtheria Prevalence and Control in the Countries of Southern Europe—Spain with a diphtheria death rate of 4.2 per 100,000 population in 1931 has experienced a steady decline in mortality from this cause since 1921 when it had a record of 14.2 deaths per 100,000. Madrid, the capital of Spain, has shown an average mortality rate of 4.4 for the years 1927 to 1931. Preventive immunization has

apparently brought forth successful results. This constructive record is in contrast to the experience of most other countries in Southern Europe.

Portugal, especially, showed a sharp increase in the mortality from diphtheria during the years 1930 and 1931 with 950 deaths in each of these years in comparison with 360 deaths in 1928. In 1930, the 2,141 cases resulted in a mortality of 45 per cent, whereas in 1928 about 16 per cent of the 2,290 cases ended fatally. This sharp rise in case fatality is evidence of the increased severity in the type of diphtheria which has been prevalent in the more recent years in Portugal. Lisbon, the largest city in Portugal, showed an average diphtheria death rate of 10.7 per 100,000 population during the years 1929 to 1931.

Greece, which has had a comparatively low death rate from diphtheria, has nevertheless experienced a steady increase in both incidence and mortality from this cause since 1924 when its low record of 192 cases and 38 deaths was reported. The year 1931 showed a record of 1,447 cases and 146 deaths, 7 times as many cases and 4 times as many deaths as were registered in the banner year 1924. The death rate from diphtheria which was 0.8 deaths per 100,000 population as late as 1928, rose to 2.3 per 100,000 in 1931. Athens, where there has been a recent rise in diphtheria prevalence, has had a doubled mortality in 1930 in comparison with 1929. Immunization has not been adopted on a large scale in Greece, but with greater confidence in its efficacy the demand for it is becoming greater.

Italy, with a continuous rise in diphtheria prevalence since 1926, registered a total of 2,968 cases (0.7 per 1,000 population) in 1930, or nearly double the notifications in 1926. In 1931, however, the number of cases declined to 24,215 (0.6 per 1,000).

Mortality records for Italy show an average rate of 7.3 deaths per 100,000 for the years 1923 to 1928. Rome, which had a diphtheria mortality of 13.6 deaths per 100,000, in 1927, has shown some reduction. The encouraging feature in diphtheria control in Italy is that the Ministry of the Interior, alarmed by the continued increase in the prevalence of this disease, has advocated immunization among all children in the primary schools.—*Bull. Hyg.*, 7:748-749 (Dec.), 1932.

Connecticut Motor Vehicle Statistics for 1932—There was a downward trend in all totals of motor vehicle statistics in 1932. The year was marked by decreases in accidents, fatalities, injuries, registration of vehicles, licenses and mileage operated on the state's highways.

Connecticut was enabled, because of some of these decreases, to achieve an enviable position in regard to the accident situation. The accident total was reduced for the fourth successive year and the injury and property damage totals for the third year, while there was at the same time a 16.6 per cent reduction in the fatality total for 1 year. The reductions are not so indicative of careful driving as the totals seem to show, however. Because of the decrease in all accidents and reduced mileage, the ratio of loss or cost per accident is actually higher in some instances, than in the previous year.

Decreases during the year included: accidents, 16.2 per cent; fatalities, 16.6 per cent; injuries, 4.9 per cent; registrations, 3.5 per cent; operators licensed, 1.2 per cent; gasoline sales, 0.9 per cent; property damage, 21.1 per cent. December was the month of most accidents during 1932. In the previous year October led in the number of accidents. The hour from 5 to 6 p.m., as in other years, was the time of most accidents in most days of the

year. There were fewer accidents in 1932 in which more than 1 person was killed, the total being 23 as compared to 37 in 1931.

The increased safety education being provided for children in the schools and elsewhere is proving its worth. Children are better trained than ever before, and on the whole, are better in traffic performance than adults. The decrease in the number of children killed was 25.4 per cent as compared to 15.1 per cent for adults. The number of children injured decreased 12.8 per cent, while the decrease for adults was 2.9 per cent.

The problem of the out-of-state driver in Connecticut accidents appears to be greater than ever before. Last year more than 15 per cent of all cars in accidents were owned and operated by residents of other states. This was an increase of 3 per cent. During the year Connecticut owned and operated cars in accidents were 18 per cent fewer while out-of-state cars in accidents were only 11 per cent fewer than in the previous year. More than one-fourth, 27 per cent of the operators involved in fatal accidents in Connecticut, were from other states.

Intoxication was a contributing factor in 291 serious accidents. The drunken operator was not the only person to contribute to this situation. Intoxicated pedestrians caused 87 accidents and these pedestrians were the greatest sufferers, as all of them not killed were seriously injured. Fifteen were killed, while deaths among intoxicated operators numbered 14.

There was an accident in every town in the state during the year, a rather unusual situation as in past years one or more towns have been free of accidents. There were 3 towns with only 1 accident. Fifty-six towns had no fatal accidents, an increase of 3 from the previous year.—Connecticut State Dept. of Motor Vehicles. *Bull.* 91, pp. 1-2.

PUBLIC HEALTH ENGINEERING

Dewatering and Incineration of Sewage Sludge Under Test at Chicago—Experiments in the treatment of sludge at Chicago with a view to eliminating digestion and sand drying beds are described. Dewatering sludge by means of a high speed centrifuge (4,000–5,000 r.p.m.) dealing with 100 gal. per min. showed a reduction of suspended matter in the effluent to 500 p.p.m. Vacuum filtration and incineration for disposal of a sludge are being investigated, ferric chloride (5 per cent) being used as a conditioner. A cake with 80 per cent moisture has been produced at a rate of 3 lb. per sq. ft. per hour. The sludge burns fairly well with little odor.

A plant handling 20 tons of solids daily comprises vacuum filter, rotary heated dryer and combustion furnace, the gases from combustion being passed through the dryer. Three hundred and fifty lb. of coal are added per ton of dry sludge. The residue is inert, contains less than 1 per cent organic matter and is free from odor. Reducing the moisture content to about 20 per cent in the dryer appears advisable. The problem of odors during incineration will probably be negligible if the temperature is high (over 1,000° F.); at temperatures of 300–500° F. odor nuisance occurs. *Anon. Eng. News-Rec.*, 109:77, 1932. From *Summary of Current Lit.*, Water Poll. Res., VI, 2:62 (Feb.), 1933.

High-Lights of Sewage Treatment in Europe—Impressions of sewage treatment in England, Holland, and Germany. In the author's opinion the progress in the utilization of sludge gas for power development as well as for heating digestion tanks is one of

the most impressive steps in sewage plant practice in England and Germany. The installation of gas engines at Birmingham and the sewage works at Motherwell, Scotland, are dealt with.

Reference is also made to the experimental activated sludge plant at Barking, aeration of sewage prior to filtration at Birmingham and the installation of two Dorr detritors with special grit removal arrangements at Wolverhampton. The Knocke-Zoute plant is briefly described; here the summer sewage is treated by settling, aeration, resettling and filtration, and the last process is omitted in the case of the smaller volume of winter sewage; a revolving brush aerator is employed and the plant operator uses the effluent for drinking water.

In Holland the treatment of trade wastes has received considerable attention; at Beverwijk a small activated sludge plant treats normally 7,000 gal. of slaughterhouse waste per day. In Germany as in America the trend is toward the complete use of mechanical equipment. The Stahnsdorf activated sludge plant at Berlin is described. The methods of utilization of sludge gas at Iserlohn, Essen-Rellinghausen, Stahnsdorf, and Wassmannsdorf are described. Users of sludge gas in Germany are compelled to odorize the gas with mercaptans. The German practice of running plants entirely on power developed from sludge gas should not be difficult to adopt in America where the gas production is much greater (0.70–1.30 compared with 0.26–0.56 cu. ft. per head per day). At Neumunster, Schleswig-Holstein, tannery wastes (1 m.g.d.) and sewage (average 4.25 m.g.d.) are treated by screening the flows separately, then allowing the

united wastes to settle for $1\frac{1}{2}$ –3 hours.

It is becoming realized that the so-called differences between American and European sewages are not so great as was formerly supposed, and that the same treatment methods, suitably modified, may be employed for both. Photographs and diagrams are included. E. B. Besselievre, *Water Works & Sewerage*, 79:157 and 217, 1932. From *Summary of Current Lit.*, Water Poll. Res., VI, 2:61 (Feb.), 1933.

New Water Works for a South American City—The occurrence of typhoid fever and dysentery in Cali, Colombia, after the introduction of the public water supply, which was obtained from the Cali River, conveyed in an open, unlined canal to an uncovered reservoir and distributed through cast-iron pipes, revealed the necessity of purifying the water. Investigations of the drainage area of the Cali River showed that the river water was liable to pollution from sewage and roads and that conditions were not favorable for effective self purification.

A plant was constructed with an initial capacity of 8 m.g.d. based on a daily consumption of 66 gal. per capita and so designed that the capacity can be increased to 16 m.g.d. This plant, details and photographs of which are given, includes weir chamber, two alum feed machines, apparatus for applying soda-ash or lime to the raw or the filtered water or both, three mixing chambers arranged in parallel, two baffled settling basins, eight rapid sand filters, chlorinators, riffle type aerator, combined clear-water basin and distribution reservoir, pumping station and wash water tank. G. C. Bunker, *Am. City*, 46, 5:75, 1932. From *Summary Current Lit.*, Water Poll. Res., VI, 1:5 (Jan.), 1933.

A Decade of Municipal Work and Improvement in Gibraltar—The

original public water supply of Gibraltar, with a population of about 20,000, was obtained mainly from a $1\frac{1}{2}$ mil. gal. reservoir allowing only about $\frac{1}{2}$ gal. per head per day during the summer, and was supplemented by a distilling plant producing 10,000 gal. per day and by private underground rain-water tanks, containing an estimated total of 7 mil. gal. and a few small wells. Since 1895 conditions have been improved by the construction of rock catchment areas of $3\frac{1}{2}$, $11\frac{1}{2}$, and 23 acres in extent, which yield about 600,000 gal. per in. of rainfall, the average annual rainfall being 33 in. Four reservoirs with a total capacity of 5 mil. gal. and another with a capacity of 2 mil. gal. have also been constructed. A brackish water supply from wells is also laid on to each house. W. H. Pearce, *Surveyor*, 81:625, 1932. From *Summary of Current Lit.*, Water Poll. Res., VI, 1:4 (Jan.), 1933.

Link-Belt Aerator-Mixer — The new Link-Belt elevated diffuser aerator-mixer, a photograph of which is given, utilizes air for agitation and can be used for the aeration tank in activated sludge plants and as a mixer in water purification. The elevated diffusers are located at one side of the tank which should be rectangular and have a maximum width of 16 ft., a maximum depth of 12 ft., and a detention period of approximately $\frac{1}{4}$ hr. Approximately 50 cu. ft. of air per min. per mil. gal. are required. The power consumption is about 0.05 kw. The velocity is regulated by valves which control the flow of air to the different tubes. Loss of head is negligible and there are no dead spaces in the mixing chambers. Alum and lime may be introduced at different parts of the mixer. R. B. Kern, *Canad. Engr.*, 62, 25:23, 1932. From *Water Pollution Res.*, *Summary of Current Lit.*, VI, 2:7 (Jan.), 1933.

MILK CONTROL SCHOOLS

W. SCOTT JOHNSON

*Chief Public Health Engineer, State Board of Health of Missouri
Jefferson City, Mo.*

SINCE the State Board of Health of Missouri adopted the Standard Milk Ordinance Program of the U. S. Public Health Service in 1925, the importance of its educational features have been increasingly evident. The value of this phase of the program was a factor in developing, in 1932, what are believed to be effective adjuncts to the previous plan of procedure.

First, in conjunction with the regular annual rating by the State Board of Health, arrangements were made to hold sanitation schools for dairymen in 8 Standard Milk Ordinance cities. In most cases, 3 or more sessions were held in each city. At these meetings, the requirements of the Standard Milk Ordinance and satisfactory compliance were thoroughly covered, and, with the aid of modern equipment, sanitary methods of milk handling on the dairy were demonstrated in detail. One meeting of the series, which the general public was urged to attend, was largely devoted to discussing the public health aspect of a community's milk supply. Advantage was taken of this opportunity to stress in each city the weaknesses of its particular milk sanitation program. A total of 1,048 dairymen

and interested citizens attended the 28 sessions of the 8 schools.

Second, in coöperation with the Department of Dairy Husbandry of the College of Agriculture of the University of Missouri, the State Board of Health held a 3-day milk control school for city dairy inspectors and plant control men. The essential points of milk sanitation and control were covered by means of lectures, laboratory exercises and field inspections which stressed particularly the requirements of the Standard Milk Ordinance. Dr. M. P. Ravenel, Professor of Medical Bacteriology at Missouri University, and Mr. M. M. Miller, Associate Milk Specialist of the U. S. Public Health Service, ably assisted as instructors the personnel of the Department of Dairy Husbandry, the State Board of Health, and several city health departments.

During the Milk Control School, the city milk inspectors perfected the organization of the Missouri Association of Milk Sanitarians and passed a resolution to continue the Milk Control School on a yearly basis. The total enrollment of the school was 41, and the milk enforcement personnel of 16 cities was represented.

New Water Treatment Plant.
Installation at Baddesley Collieries
—An illustrated description of a Paterson water-softening plant installed at the Baddesley collieries to treat a supply composed mainly of pit water with no permanent hardness but a variable amount of temporary hardness. To this, when necessary, well water of 17.2 gr. per gal. temporary and 6.5 per gal. permanent hardness is

added. The supply is used for boiler feed and make-up water and for pit-head baths and the plant is capable of treating a maximum of 7,500 gal. an hour.

The pit water requires treatment with lime and alumina, which must be supplemented by soda ash when well water is added. The water entering the plant is divided by an adjustable weir into a major and a minor flow propor-

tioned according to the hardness of the water. The major flow drives a water wheel which operates agitators in the chemical solution tank and the reaction and precipitation tanks. The minor flow passes through an "osilameter" which operates a reagent measuring bucket discharging the quantity of reagent necessary for treating the whole supply. Heavy sludge is deposited on the cone-shaped bottom of the reaction tank and discharged, and lighter impurities are removed by upward filtration through a wood-fibre strainer. *Iron & Coal Trades Rev.*, Anon., 1932, 125, 238. From *Summary of Current Lit.*, Water Poll. Res., VI, 1:2 (Jan.), 1933.

Sterilizing Mains and Contaminated Pipe—The cleaning and brushing out of pipes and protection from contamination during the laying process makes subsequent sterilization more effective. The New York Water Department requires sterilization of new mains by addition of enough calcium hypochlorite to the water entering the pipe to produce a chlorine

content of at least 3 p.p.m. If after standing for several hours and blowing out, the bacterial tests are unsatisfactory, a field chlorinator, whose construction and mode of action are described, must be used. The equipment should be installed on the highest possible point on a new main where a connection between the existing distribution system and the new main is available. The chlorine content, examined at hydrants by orthotolidin standards, should not exceed 3 p.p.m. on account of chemical reaction with the pipe coating.

After about 4 hours the machine is stopped and the chlorine solution allowed to waste slowly through the blow-off. When no residual chlorine is left bacterial tests are again made. The joints in large mains should be painted with saturated chlorine solution to aid penetration of the disinfectant into crevices. Similar precautions against contamination must be taken in repair work. W. W. Brush, *Canad. Engr.*, 63, 13:13, 1932. From *Summary of Current Lit.*, Water Poll. Res., VI, 2:41 (Feb.), 1933.

INDUSTRIAL HYGIENE

Industrial Disease Commission Starts Job—The newly appointed Commission on Industrial Diseases held its first meeting October 11, 1932. According to the statement by Governor Pinchot the Commission is composed of 10 members to represent the largest interests affected by any steps toward compensation for occupational diseases, and were chosen for their eminence and expertness and long practical experience in this field. The members are: A. M. Boyd, Alexander Fleischer, Wesley Graff, Thomas Kennedy, A. J. Lanza, R. V. Patterson, Louis B. F. Raycroft, H. F. Smyth, T. Henry Walnut and W. P. Yant.—*Month. Bull. Pennsylvania Dept. of Lab. & Ind.*, 19, 9:7 (Oct.), 1932.

E. R. H.

"Occupational Diseases"—Nearly all the European compensation laws and the laws of Illinois, Kentucky, Minnesota, New Jersey, New York, Ohio, and Porto Rico, list the occupational diseases which are compensable. In Connecticut, "occupational diseases" are defined, while they are undefined in the Longshoreman's Act and the District of Columbia.

All injuries to health arising out of the employment are compensable in California, Massachusetts, North Dakota, Wisconsin, Hawaii, and the Philippine Islands. For some 8 years—from 1919 to 1927—the Connecticut law was also in this class. In California, however, where the employment aggravates a preëxisting disease, only the aggravation shall be compensable.

There is no reported experience of awards other than "accidental" injuries in North Dakota, Hawaii, or the Philippine Islands. Consequently our

only experience with compensation for all "injuries" arising out of employment, whether "accidental," "occupational," or otherwise, has been in Connecticut, Massachusetts, and Wisconsin.

In Connecticut, "occupational diseases" are defined, in general terms, to include only the diseases "peculiar" to the occupation. Compensation is denied for aggravation of vice diseases and is "pro-rated" for acceleration of other diseases, while the provision permitting "waivers" due to preëxisting infirmities is broadened.

"There is a strongly organized movement for the general adoption of this mislabeled 'all inclusive method of covering occupational diseases.'" The International Association of Industrial Accident Boards and Commissions has endorsed it. And it is being widely represented that its adoption would add only 1 per cent to the cost of insuring compensation for "accidents" only. "But there isn't the shadow of a basis for such representation as to the cost." The cost of compensation for diseases is steadily rising, as in Wisconsin from 1.2 per cent in 1924 to 2.1 per cent in 1929. Such data as the National Council on Compensation Insurance has collected would indicate a loading of 3.5 per cent on pure premiums to meet the cost of occupational disease coverage. In contrast, the experience in New South Wales indicates that in certain occupations the cost of silicosis alone is somewhere between 7 and 10 per cent of payrolls. In Ontario, however, under the "schedule plan," it seems that, with emphasis on prevention rather than compensation, silicosis is being covered at a much lower cost.—From

Ominous Abuses Threatening the Insurability of Workmen's Compensation, by F. Robertson Jones, Gen. Man., Assn. of Casualty and Surety Executives, 1 Park Ave., New York City (Sept. 8), 1932, pp. 13-15. E. R. H.

Occupational Disease and Compensation—There are at the present time 27 occupational diseases in the New York Compensation schedule. For the year ending June 30, 1932, there were 655 claims of which 288 were disallowed, 196 awarded, with the balance pending or otherwise disposed of.

Of the total, 114 were due to lead, 113 to dyes, 67 to cleansers of one type or another, 34 to oil and grease, and the balance scattered through various headings. A detailed table shows the claims classified according to occupations and disposition of cases; another table, according to disease and disposition of cases; and another table according to disease and industry. A total of 163 occupations were represented. Most of the cases of dermatitis were listed under domestic and personal service and in the food industry. Lead poisonings were found almost solely in the metal and the building trades. Benzol poisoning (including dermatitis) was confined to the handling of dyed materials in the fur and clothing industry. Marked gaps still exist in the compensation law which result in great economic losses to workers.—Frieda S. Miller, *Indust. Bull.*, New York Dept. of Labor, 11:12-13 (Sept. and Oct.), 1932. E. R. H.

Silico-Anthracosis—A century ago the dangers of inhaling coal dust were accepted. At a later period, associated with a discovered low tuberculosis rate, they were discountenanced. Today, the dyspneic coal miner with his constant cough, associated chronic bronchitis and emphysema, black lung,

resistant and airless parts, with or without pleural effusion or abscesses, and with an abnormally high silica content, is again becoming of serious concern.

Historically, these phases have been associated with the names of Pearson (1813), Thomson (1837), Stratton (1838)—who devised the term "anthracosis," and Greenhow (1869) who extracted 30 per cent of silica from the lung ash of a collier who had died from miners' phthisis. Virchow (1858), however, convinced himself that the pigment in the lungs was not inhaled carbon but altered hemoglobin and therefore endogenous in origin and even Jousset (1928) expressed the same view. Villaret (1862) propounded the idea that anthracosis came not by inhalation but through the intestinal route and Calmette (1907) and his pupils reiterated this view. However, Vincent (1907), Basset and Cave (1907), Cobbett (1910) and Findlay (1911) were unable to produce pigmentation of the lungs by feeding animals with soot or pigments, but they did produce pigmentation by inhalation. Thus, anthracosis today is considered as caused by inhalation only.

While it is probable that the recent work of Cummins and Weatherall (1931) explains the immunity to tuberculosis on the basis that coal dust absorbs the active principle of tuberculin, the other gross pathology—bronchitis, emphysema and fibrosis—must not be forgotten. Nor are the finer particles of dust alone responsible, since, in asbestos workers, particles measuring from 40 to 100 and even up to 360 microns in length have been encountered within pulmonary alveoli.

Oliver (1909), Collis (1915), Tattersall (1926), and others have also proved beyond reasonable doubt that there is a serious impairment of lymph drainage in the lungs of coal miners by the action of silica.

A case history with autopsy is described of typical "silico-anthracosis" in a soft coal miner who had no other employment throughout a long life and whose lungs showed extensive fibrosis, occasional fibrous whorls, emphysema, carbonaceous deposits, and masses of golden yellow pigment, as well as black angular particles measuring from 10 to 80 microns in length. In many respects, curious bodies were seen which have been considered typical of asbestosis only. Still, the case in question had had no exposure to strata containing iron ore or large amounts of silica. The constancy of the peculiar bodies in asbestosis is therefore questioned.

The present case lends strong support to the theory that anthracosis is primarily a silicosis and that it occurs not only in hard coal miners but also in workers in soft coals.—W. E. Cooke, *J. State Med.*, 40, 12:702-708 (Dec.), 1932. E. R. H.

Cleanliness in Industry—This is an address presented before the Annual Convention of the Linen Supply Association of America held at West Baden, Ind., May 26, 1932.

Disraeli, the great English statesman, said, "Although it is humiliating to confess, yet I do confess that cleanliness and order are not matters of instinct; they are matters of education and like most great things, mathematics and classics, you must cultivate a taste for them."

Definitions are given and the article discusses personal responsibility, the bettering influence of woman in the case, workplace cleanliness, more stress upon health, industrial diseases and personal cleanliness, special wearing apparel, indoor clothing and health, light and health, sanitary laws and regulations, cosmetics and cleanliness, and the necessity for publicity.

It was found by a medical director

of a large automobile company in Cleveland that "machinist's boils" could be effectively prevented by supplying workers liberally with cloth towels for the purpose of frequent mechanical cleansing of the hands and arms from grease and dirt. An argument is also presented for the use of special clothing of durable and washable nature, such as linen suits, aprons, caps, etc., for use in many industrial processes.

It is concluded that cleanliness in industry promotes health, safety, and efficiency. It revolves about conservation measures of relative importance. It is secured less by appeal to reason than appeal to pride and idealism. Definite rules for guidance should be set up. Education by various methods should be a consistent and persistent feature. Discipline and penalties are important but secondary to incentive and appeal. This means organization, planning and supervision. Leaders and leading plants should set examples and make demonstrations. Education and publicity should be upon a research basis which will develop facts. Everything which succeeds runs the gauntlet of severe competition. Ruskin once said "There is hardly anything in this world that some men cannot make a little worse and sell a little cheaper."—Emery R. Hayhurst, *Annual Report*, Linen Supply Assn. of America, 1932, pp. 23-30. E. R. H.

The Employment of Women in Vitreous Enameling—This is a study of the enameling departments of about 50 plants, practically all making stoves, and of home interviews with nearly 700 women employed in those plants at the time or within the 12 months preceding the interview. The survey was made with the coöperation and scientific assistance of Dr. Alice Hamilton.

The workers are to a great extent youthful, more than three-fourths being

under 30 years and more than one-fourth under 20. In some places the work is done with a leadless glaze, thus obviating a definite hazard. Two groups of women make up the larger number of employed in this enamel work—sprayers and brushers. The former are much more exposed to lead, also much of their work is done on cast iron having a cover of lead enamel, while the latter are chiefly employed on sheet iron for which a leadless enamel is generally used.

Over 50 per cent more sprayers than brushers complained of metallic or sweetish taste, indigestion, constipation, and menstrual disturbances, while they also had a higher rate of absences due to ill health (than the brushers). Nearly one-fifth of the sprayers had left work because of illness while less than one-tenth of the brushers gave illness as the cause. While no definite evidence of lead as a race poison was ascertained—sterility, miscarriages, stillbirths, and infant deaths—the data on this point correspond significantly.

Strict medical supervision is recommended, also adequate provisions for cleanliness. In a great majority of states the statutes are quite inadequate to cover this hazard. Leadless enamels should be furthered.—*Fourteenth Annual Report*, Director of the Women's Bureau, 1932, pp. 5-7. E. R. H.

Occupational Diseases in Germany—According to German official statistics for 1930, the number of cases of occupational diseases in that year was 5,920 in industry, 937 in public institutions and 7 in agriculture.

Occupational diseases in industry represented 0.84 per cent and those in public institutions 1.08 per cent of the total number of accidents and illnesses occurring in these two branches respectively.

The number of cases compensated in 1930 was 647 in industry, 118 in public

institutions and 4 in agriculture, the percentages in relation to the total numbers of accidents and illnesses compensated being 1.48 in industry and 1.52 in public institutions. The number of cases of occupational diseases followed by death was 94 in industry and 13 in public institutions.

In mines the number of cases of sickness compensated for the first time in 1930 was 1,795. The number of fatal cases was 356.

The most frequent occupational diseases were lead poisoning (2,215 cases reported, 269 compensated and 8 fatal in industry); silicosis (1,719 cases compensated and 352 fatal in mines; 848 reported, 202 compensated and 1 fatal in industry); infectious diseases (562 cases reported, 19 compensated and 8 fatal in industry; 696 reported, 87 compensated and 10 fatal in public institutions); and carbonic acid poisoning (644 cases reported, 46 compensated and 32 fatal in industry).—*Indust. & Labour Inf.*, XLIII, 11: 355-6 (Sept. 12), 1932. E. R. H.

Patologia da Solventi e Misure Igieniche e Profilattiche (Relazione)—This bulletin of 19 pages, from the 10th National Congress on Industrial Medicine held at Milan, April, 1932, carries 5 extensive infold tables pertaining to critical data on no less than 125 solvents and diluents of industrial significance from the point of view of toxicity. There is also a special discussion of the combinations of cellulose, or solvents in general, plastics, diluents and pigment colors, and a short bibliography.—Professor L. Carozzi, Milano, *Tipografia Antonio Cordani S. A.*, 1932—X. E. R. H.

The Control of Discharged Gases and Fumes from Ventilating Systems—An illustrated article giving the chief features to be considered in preventing the return of discharged gases

and fumes into the working quarters, and the protection of the public. Special description is given of a method for controlling the fumes of nitric acid and its oxidation products.—John Vogt, *Indust. Bull.*, New York Dept. of Labor, 11, 12:367-8 (Sept.), 1932.

E. R. H.

Governor's Health Commission Industrial Recommendations—In 1930, the Governor appointed an informal commission of 14 members to study and report upon the administrative and legislative aspects of public health in New York State. The committee found, so far as industrial relations go, that there were 60,000 workplaces and over 3,000,000 industrial workers in the state; also, that the state expends \$36,000,000 annually on compensation, and only \$800,000 on prevention. The various recommendations and comments of the Committee on Industrial Hygiene are discussed in brief.—Adelaide Ross Smith, *Indust. Bull.*, New York Dept. of Labor, 11, 13:400 (Oct.), 1932.

E. R. H.

The Medical Aspects of Industrial Accidents—This article (in English) considers in detail various working conditions, the worker, and social conditions considered provocative of industrial accidents. It seems inconceivable that at a time when industrial establishments and organizations claim to be "scientific" in their methods, 36.5 per cent of accidents are still attributable to undetermined causes, 26 per cent to causes incapable of elimination, and 45 per cent to unforeseen causes. It is maintained that no little part of this discrepancy lies in the predisposing causes discussed in the body of the paper.

A safety service in industrial establishment is, of course, of value, but a study of the "human factor" and the influences motivating him or failing to

motivate him is of far greater importance. A lesson should be taken from the methods used in the selection of candidates for aviation work.—L. Carozzi and A. Stocker, *Arch. f. Gewerbepath. u. Gewerbehyg.*, 4, 1: 14-41, 1932.

E. R. H.

Medical Service in a Chemical Industry—This article by the Medical Director, E. I. duPont de Nemours & Co., discusses the matter of selection, protection, and treatment of workers exposed to various chemical poisons, with a summarizing statement as follows: (1) Every industrial physician should have a working knowledge of his entire plant; (2) every new employee should be carefully examined and selected in such a manner as to enable him to work efficiently, safely, and without undue injury to his health; (3) every industrial physician should protect the health of his workers by (a) frequent periodic examinations, (b) frequent inspection of the working conditions in the plant; (4) treatment is dependent upon early detection with immediate correction of the cause or removal of the worker; and (5) the entire service is dependent upon three principles: selection, protection, and treatment.

A valuable 3-paged discussion by various industrial physicians, hygienists, and research workers follows, concerning rayon, sulphuric acid, solvents for Duco, carbon tetrachloride, tetraethyl lead, and especially methanol.—G. H. Gehrman, *Bull. Am. Assn. of Indust. Phys. & Surg.*, 6, 2:1-7 (Oct.), 1932.

E. R. H.

Silicosis in the Foundry—This is a rather extensive bulletin on the subject of the characteristics, control, and compensation of silicosis as related to foundry work. The types of dusts, how silicosis is produced, special features about silicosis, its stages and progress,

dangerous concentration of silica dusts, and treatment, comprise Part I.

Part II is devoted to control of silicosis in the foundry, suggesting a tentative program in casting cleaning operations. Part III goes into detail in the matter of compensation with a discussion of blanket coverage for occupational diseases, the Ohio situation in which the claimant with silicosis is helpless under the present state law, shifts in position as respects jury decisions, incentives to systematized compensation, "no specialized legislation is needed for silicosis," silicosis is unlike other occupational diseases, meeting the silicosis claim, and special features for silicosis as regards compensation.

In the discussion, E. O. Jones, of the Belle City Malleable Iron Company, Racine, Wis., recites in interesting detail the recent history of the industrial aspects of silicosis in that state, and the attempt to meet the situation, which is involving an enormous total for claims, through a code prepared by the Industrial Commission covering dust, fumes, vapors, and gases. It is felt that the most effective way to meet the challenge is through prevention and control—in other words, Good House-keeping.—Carey P. McCord, *Spec. Bull.*, National Founders' Assn., 29 S. LaSalle St., Chicago, 1932, 46 pp.

E. R. H.

Silicosis—This brochure of 21 pages is written especially for the use of persons interested in the protection of industry and its employees. It discusses the nature of silicosis and related dust effects upon the lungs, how silicosis is contracted, how detected, and the compensation experiences in the laws of various countries; likewise, how industry can protect itself and its employees, and the essentials to be considered in the defense of claims. The brochure is pitched in language adaptable to the

intelligent layman.—C. O. Sappington, 1932, *Industrial Relations*, 844 Rush Street, Chicago.

E. R. H.

Pneumoconiosis—The authors direct attention to pneumoconiosis arising in connection with grinding and polishing of metals by artificial abrasives, particularly emery wheels. At present such work is not included in the schedule of occupational diseases for which compensation is allowed (England and Wales).

Six case reports are detailed, 4 with post-mortem findings, to support the contention that dust from occupations other than those included in the schedule may cause pulmonary fibrosis and produce a condition clinically and pathologically indistinguishable from silicosis. Reference is also made to the findings of Middleton (1923) that emery dust may give rise to pulmonary fibrosis. It seems advisable therefore to safeguard those who are employed in grinding and polishing metals with artificial abrasives.

The necessity for necropsies by skilled pathologists is emphasized in order to bring to light more information on deaths among those suspected of having pneumoconiosis.—J. R. Todhunter and G. B. Dixon, *Lancet*, 5699: 1123-1126 (Nov. 19), 1932.

E. R. H.

Pneumoconiosis—The only general inference which can be drawn on the present information of the Factory Department of the Home Office is that fatal cases of fibrosis of the lungs occur in those industries in which there has been a risk of exposure to silica or asbestos dust.

This is not to say that exposure to dust of artificial abrasives may not cause disablement or death—only that the case is not established. While there are some thousands of persons engaged in occupations involving the use of artificial abrasives, there does not appear at present to be any conclusive evidence to show

that disablement or death from pulmonary disease follows as a result of such employment.

The group "metal glazers, polishers, buffers and moppers" does not represent a pure exposure to artificial abrasives since many have worked on grindstones and inhaled silica dust so that statistics of this group do not reflect the effect of artificial abrasives.—John C. Bridge, H. M. Senior Medical Inspector of Factories, *Lancet*, 5701:1249-1250 (Dec. 3), 1932.

E. R. H.

Soda and Its Compounds—The ammonia-soda process is described and illustrated by chart as well as the extent of operations in the United States and Canada. The health conditions found in 5 plants are given, followed by a more detailed discussion of the manufacture of soda ash and caustic soda by the LeBlanc and the electrolytic processes. The potential health hazards are considered to be: dampness, fumes and odors from ammonia and carbon dioxide gas and carbon monoxide, and dust. The resulting occupational diseases involving the skin and the mucous membranes as well as the nervous system are reviewed from standard works as well as from a report by C. C. Payson of the Connecticut General Life Insurance Company. A classification and index of jobs shows the chief hazard in connection with each.—*Industry Report*, Retail Credit Co., 7, 11:127-137 (Nov.), 1932.

E. R. H.

Chrome Poisoning Outbreak—Although chrome poisoning has been named as an occupational disease in the New Jersey workmen's compensation law since 1924, no claims therefor

were ever made until early in 1932. Suddenly, 95 claims were filed from employees in the same chemical plant, nearly all of whom were "laid off." Medical questions were by mutual agreement referred to two specialists as medical referees and their findings were made the basis of the awards. The awards averaged \$500 payable in installments of \$20 per week for 25 weeks, based upon an average rating of 5 per cent disability. Fees to the applicants' lawyers and doctors, including the medical referees, were limited to 25 per cent of the amounts of the awards, payable one-half each by the beneficiaries and the employer respectively. The nasal passages were (apparently) the chief location of damage.—*Newark Evening News*, June 6, 1932, quoted by the *Bulletin, Assn. of Casualty & Surety Executives*, 31:7-8 (Oct.), 1932. E. R. H.

The Health of Chromium Plating Workers—The article discusses chromium plating as a commercial undertaking in the past 6 years and the occurrence of various occupational diseases, such as chrome holes, nasal ulcerations, dermatitis, and certain constitutional symptoms of which vomiting is the most prominent; also, the prevention of the ill effects encountered.—H. B. Trumper, *J. State Med.*, 40, 12:696-701 (Dec.), 1932. E. R. H.

Workmen's Compensation in Pulmonary Disease—A description of the various British Acts and Schemes covering compensation for industrial pulmonary disease, especially silicosis and asbestosis.—Charles L. Sutherland, *J. State Med.*, 40, 12:709-716 (Dec.), 1932. E. R. H.

FOOD AND NUTRITION

Cobalt in Animal Nutrition—As a result of experiments reported previously (*A.J.P.H.* 22:664, June, 1932) that a polycythemia was produced by the addition of cobalt to a milk-iron-copper diet, a study was made of the cobalt content of normal rats and those in which a polycythemia had been produced by cobalt feeding. A rapid colorimetric method for the estimation of cobalt in biological materials is given. This is applicable to a sample containing 0.01 to 0.5 mg. of cobalt. In an attempt to detect cobalt in the body of an animal which had been fed cobalt, rats were fed a basal diet of milk fortified with iron, copper, and manganese sufficient to supply each rat with 0.5 mg., 0.05 mg., and 0.04 mg., respectively, per day. Some rats remained on the basal diet while others were given cobalt in amounts varying from 0.1 to 2.0 mg. per rat, daily. In no case was cobalt definitely detected in those rats receiving added cobalt. With young rats receiving more than 0.6 mg. of cobalt per day the rats rapidly lost weight and at 2.0 mg. the rats survived only for a period of 2 weeks.

For the study of the distribution of cobalt in the tissues, pigs were used because they could be fed larger amounts and the organs offered larger samples for analysis. Four pigs were given only whole cow's milk *ad libitum* to which were added daily 25 mg. Fe, 5 mg. Mn, and 2 mg. Cu. Two pigs received in addition 25 mg. of cobalt.

The pigs were 2 weeks old when the experiment was started. One pig from each diet was killed at the age of 7 weeks and the other 2 were killed at 12 weeks. Cobalt was found to be relatively absent in the tissues of the pigs which received no cobalt. In those receiving cobalt, the greatest amount was

found in the liver, pancreas, and spleen. The vertebrae and ribs contained 1.98 mg. of cobalt per kilo of dry material and the long bones contained an amount undetectable. It is suggested that perhaps the vertebrae and ribs are more active in erythrocyte formation and this may be where cobalt exerts its effect in producing a polycythemia. F. J. Stare and C. A. Elvehjem, *J. Biol. Chem.* 99:473 (Jan.), 1933.

The Effect of the Prolonged Feeding of a Milk-Iron-Copper Diet to Rats—Three groups of rats were studied. The animals in Group I were placed in individual glass cages at the weaning age and were fed whole milk *ad libitum*, supplemented by 0.5 mg. of iron and 0.025 mg. of copper 6 days a week and were continued on this diet until they were 346 to 395 days of age. All of the rats showed erythrocyte counts only slightly lower than those of the control animals. The body weight averaged 317 gm. Autopsies revealed no gross abnormalities. The animals in group II were kept on the milk-iron-copper diet from the time of weaning until they were from 450 to 454 days of age. The hemoglobin, erythrocyte and cell volume values were almost identical with those found in group I. Autopsies showed no gross abnormalities.

The animals in group III at time of weaning were placed on an exclusive whole milk diet until a severe nutritional anemia developed, when supplements of iron and copper were added. 6 days a week. One rat received 0.05 mg. of copper and one received 0.025 mg. of copper. Both promptly recovered from the anemia and were continued on the milk-iron-copper diet until they were 667 days of age. Al-

though the rats in group III were about 11 and 7 months older than the rats in the other groups, the blood findings agree with those found for the first two groups. In general, all of the animals appeared to be in good nutritive condition. While these results cannot be regarded as final evidence for the completeness of an exclusive milk-iron-copper diet for rats, the data indicate that such a diet will maintain rats in an apparently normal condition for long periods of time.—F. Aline Underhill, James M. Orten, Edward R. Mugrage, and Robert C. Lewis, *J. Biol. Chem.* 99:469 (Jan.), 1932.

A Note on the Calcium Content of Cabbage—Great variations in the calcium content of cabbage leaves from different parts of the plant were found during the course of feeding experiments. Samples were obtained in the market during the month of June. The heart leaf ran reasonably uniform during 5 experiments, the variation in calcium running from 26 to 32 mg. per 100 gm. of moist leaf. The inner pale green leaf varied from 35 to 71 mg. while the outer dark green leaf varied from 476 to 1,058 mg. on the same basis. The latter figure represents more calcium than is found in any other common food, except cheese. Reference is made to the fact that food analysis tables in common use do not mention the high calcium values in the outer leaves of cabbage.—Stuart Jasper Cowell, *Biochem. J.* 26:1422, 1932.

Mussel and Clam Poisoning—In 1927, there were 100 cases of mussel poisoning and 7 deaths. Since that year the California Board of Public Health has quarantined mussels during the summer months when these are toxic, the period of embargo terminating September 30. The poisoning was studied by Dr. Meyer of the Hooper foundation for Medical Research, who

found that shellfish become toxic during the spring and summer but not toxic during the winter months, the peak of toxicity occurring in July. In experiments performed at the Foundation, it was found that mussels, particularly toxic to animals, could be rendered less toxic by cooking in bicarbonate of soda; $\frac{1}{4}$ ounce of soda to each quart of water destroyed 85 per cent of the poison if cooked 20 to 30 minutes. It was found that clams may be equally toxic but that fewer cases of poisoning are reported owing to the fact that the intestines of the clams are generally discarded.—Weekly Bulletin, California Dept. of Public Health, 12:7 (Feb. 11), 1933.

Increasing the Vitamin D Content of Milk. II. The Effect of Feeding Cows a Cod-Liver Oil Concentrate (Vitex)—A previous paper reported the effects from feeding large amounts of irradiated ergosterol to cows (*A.J.P.H.* 22:1004, Sept. 1932). This work reports the use of a cod liver oil concentrate commercially known as Vitex. Holstein cows were used and were fed on a basal ration of beet pulp, corn, oats, wheat bran, linseed oilmeal and salt. After 17½ days on this ration, milk and fat production was calculated and the cows divided into groups so the total milk and fat production was approximately equal.

Five feeding periods of 21½ to 32 days were employed for both groups, alternating the basal ration the first, third, and fifth periods with Vitex in the second and fourth. At the end of each period the cream was churned into butter and pure butterfat used for vitamin D assay. Some increase in the vitamin D was observable with all additions and the increase directly proportional to the amount of vitamin D fed. When 60,000 rat units were fed the milk contained 30.35 Steenbock rat

units compared to 2.76 rat units per quart without vitamin D feeding. No adverse conditions were noted during the Vitex feeding and apparently no other effect in the milk and fat production except the decrease which the authors regard as normal toward the end of lactation.

Comment is made that the increased

potency, 30.35 rat units per quart, is much below the 160 units generally recommended for rachitic infants. Furthermore, the cost of Vitex feeding renders this source of vitamin D as impracticable.—W. E. Krauss, R. M. Bethke and Willard Wilder, *Bimonth. Bull.*, Ohio Agri. Exper. Sta., 18:15 (Jan.-Feb.), 1933.

CHILD HYGIENE

MILK FOR CHILDREN IN THE EMERGENCY

EVIDENCE is accumulating which points to serious nutritional disturbances among large numbers of our preschool children. Undoubtedly this is the group which is suffering most during the depression. It is difficult to secure social control of these children and to make certain that they are getting an adequate and balanced ration. Recent examinations of such children in day nurseries and preschool centers indicate a relaxation of nutritional standards among them.

The greatest lack seems to be in their daily consumption of milk, which has dropped, in some places, to less than a pint a day. Milk is supremely important in this age group. At least 1 quart a day of milk should be assured to every preschool child. At present the child has to take its chances in securing enough milk from the family ration. The relief agencies, on the whole, are not furnishing enough milk to families with 2 and 3 preschool children.

In recommending quantities of milk to be used in the low-cost diet, the U. S. Department of Agriculture stipulates:

... 1 quart of milk daily from early childhood to adolescence, and 1 pint or more daily for the adult. For a family of 5 consisting of father, mother, and 3 children under

14 years, this makes a weekly milk order of 28 quarts. When shortage of money forces the expenditure for food to an abnormally low level, the proportion spent for milk should be increased.

Many families are receiving not over 8 or 10 quarts of milk per week. This is entirely too low for the optimum nutritional needs of children. A recent bulletin from the National Dairy Council observes that

... when properly approached, relief agencies are readily convinced of the practical necessity and economy of milk in the relief food budget. For instance, in Chicago the expenditure for milk has been increased to about 30 per cent of the food dollar. This assures a pint of fresh milk for every child. While not an adequate amount it is a step nearer the nutritional standard used in most cities. The Chicago Milk Foundation has been instrumental in bringing about this division of the Chicago food relief dollar.

The National Dairy Council recently has made a survey of the expenditures for relief work last year in some of the cities with local dairy councils. It reports that

... it is evident from replies received that the amount for unemployment relief appropriated in some Dairy Council cities during the period July, 1931-June, 1932, is very impressive. It has been impossible to obtain complete figures in all Council cities. However, in 17 city centers, having a total population of 13,243,328, \$75,437,208 was spent for relief work. Of this amount, ap-

parently about \$12,220,000 was appropriated by the States, the balance being city appropriations and volunteer contributions.

But when we try to find out how nearly the food portion of this budget was expended in accordance with good nutrition standards, it is necessary to take figures from a few cities in which methods of distribution make such records available for this study. If we accept the average of several cities as conservative estimates, then 75 per cent to 90 per cent of the relief funds was spent for food and the balance for housing, clothing, medical care, etc. Of this food expenditure, the proportion used for fresh milk varied from 2 per cent to 16 per cent. In only two cities reports indicate the higher figure. In this connection it is interesting to note that the expenditure for milk is greater in all Council cities than in a number of comparable cities without Council work.

In a study of food order of 2,558 Associated Charities families in Cleveland, Ohio, during one week in December, 1932, it was found that of the total order of \$7,959.03, \$903.85 was spent for fresh milk, \$406.94 for evaporated milk, and \$13.35 for buttermilk. In other words, 16.63 per cent of the total food bill was spent for milk. Reduced to quarts this would mean about 8 quarts per family per week. It is recognized that some milk was delivered directly to the families; but this was not enough to affect seriously the figures given.

The National Dairy Council bulletin continues:

The dairy industry is very vitally interested in the proportion of the emergency relief food dollar that is being spent and will be spent for fresh milk. The milk producer and dealer are most directly affected, but the matter has an important bearing on the total expenditures of relief agencies for all dairy products. The extensive preparations for increasing such relief in the winter of 1932-1933 bring the matter into special prominence at the present time.

This year with national and state participation, there will be greater overhead control; therefore, greater uniformity of procedure and fewer officials with whom to deal. This offers the fresh milk industry a distinctly greater opportunity than last year to influence authorities to utilize more fresh milk

in relief work. The total consumption of all forms of milk in emergency relief is now much below even minimum nutrition standards. Nutrition authorities are agreed that for an adequate diet at least one-fifth of the food money should be spent for milk. This standard set by Dr. Sherman was qualified by him last winter in a bulletin, *Emergency Nutrition*, in which he stated, "When shortage of money forces expenditure for food to an abnormally low level, more than one-fifth (perhaps one-third) should therefore be spent for milk in some form."

The comparative economy of fresh milk can be readily demonstrated to open-minded officials. In almost every city there is already a nutritional committee or group to whose prominence the welfare people will give careful attention. In some cities these committees are an integral part of the welfare organization.

The objective of the milk industry is to secure the expenditure for fresh milk of not less than \$.20 of each 1932-1933 food relief dollar. According to present information, the amount of money that will be spent for food through relief agencies will total three-quarters of a billion dollars.

In the October 1932 issue of the *Dairy Council Digests* the importance of milk in the child's dietary during a period of national distress is clearly set forth:

Experience as well as research has proved the wisdom of laying particular stress upon the diets of children. Curtailment of children's diets in European countries during the World War was followed by outbreaks of dietary deficiency diseases. It is a well known fact, however, that serious undernutrition may result even when such deficiency diseases do not threaten. The American Medical Association points to the fact that, "Prolonged general underfeeding may often be more insidious in its effects than are specific inadequacies that result in such diseases as scurvy, rickets and pellagra." This fact has been recently demonstrated by the condition of children in Germany. Observation on nearly 4,000 school children shows that classes starting in 1924, 1925, and 1926 are not making progress in their school work that classes starting later are making. The difference is ascribed by the City Health Department of Berlin to the fact that the former children were born during the war years, 1917-1919, in which their nutrition was especially inadequate.

Under the most favorable circumstances, a wise selection of food and the proper feeding of a family requires knowledge and skill. But when every dollar must bring the greatest return in nourishment and satisfaction, the task becomes more difficult. In the present economic crisis, with its resulting reduction in income and employment, the problem of obtaining an adequate diet at a minimum cost has become a universal one.

It has been well said that, "A time of emergency is an excellent period in which to teach the scientific lessons that necessity forces on us." And the "teachers" who have responded in the present "necessity" are those leaders in nutrition who represent public and private agencies interested in the health and well-being of the people.

It is fitting that the U. S. Government Bureaus took the initiative early in the depression period in pointing to the necessity of spending the "food dollar" properly if it was to protect the health of citizens. Other agencies rapidly followed the lead in the crusade for adequate diets and sounded a warning to nutrition leaders of the consequences of relaxing their vigilance in maintaining dietary standards. From the first, these agencies have urged that food money be spent for food that would "feed" not merely

"fill," and that the so-called "protective" foods—milk, fruit, vegetables and eggs—be accorded their rightful place in emergency diet.

Research studies have long since established, and recently confirmed, the fact that a child requires 1 quart of milk daily for the satisfactory growth of the bones and teeth. One pint of milk covers the adult's daily need. A question frequently asked at this time is, "Does the fact that the food fund is reduced alter this rule?" Dr. Sherman answers this question, in effect, when he says that, in cases where the food fund is reduced to a minimum, "The dietary should be built around bread and milk. The lower the level of expenditure," he continues, "the more one must forego other foods and concentrate effort upon providing these two, supplemented by a little of some inexpensive fruit or vegetable."

Gillett and Rice found that city families added to the nutritive value of their diets without increasing the total cost when they bought more milk and cheese. Families spending 25 per cent of the food fund for milk and cheese obtained a diet higher in calcium and in vitamin "A" and for less total outlay of money than when only 19 per cent of their food fund was spent for milk and cheese.

PUBLIC HEALTH NURSING*

Our Rôle in Communicable Disease Control—The nurse's main objects in a communicable disease program are control and prevention. To attain these objects she must know five fundamental factors:

First, what communicable diseases account for the greatest number of deaths? The White House report gave the following communicable diseases in the order named accountable for the greatest number of deaths under 20 years of age: bronchopneumonia, tuberculosis, lobar pneumonia, diphtheria, whooping cough, influenza, measles, typhoid fever, pneumonia, syphilis,

scarlet fever, dysentery, meningococcus meningitis, malaria, poliomyelitis, tetanus, epidemic encephalitis, gonorrheal infection, mumps, smallpox, and rabies.

The degree of disability caused by the disease, the prolonged convalescent period, and the resulting handicaps, are other important factors besides death which determine the seriousness of the disease.

Second, which of these diseases should be selected for concentration of effort in control and prevention? Usually tuberculosis, diphtheria, whooping cough, measles, typhoid fever, syphilis, scarlet fever, and smallpox are the ones most commonly selected for this purpose.

Third, at what age is death most

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

prevalent from these communicable diseases? (White House Conference *Report of the Registration Area of the United States for 1926, 1927, 1928*).

| | Per Cent Total Deaths Under 20 Yrs. | Per Cent of Deaths Under 1 Yr. | Per Cent of Deaths Under 5 Yrs. | Per Cent of Deaths Under 10 Yrs. |
|----------------|---|-----------------------------------|------------------------------------|-------------------------------------|
| Tuberculosis | 16.0 | 1.5 | 4.5 | |
| Diphtheria | 94.3 | 7.0 | 58.5 | 86.5 |
| Whooping cough | 99.6 | 57.2 | 95.9 | 99.1 |
| Measles | 94.5 | 24.9 | 76.4 | 88.2 |
| Typhoid fever | 39.4 | 0.6 | 4.7 | 11.7 |
| Syphilis | 24.5 | 18.9 | 21.3 | 21.9 |
| Scarlet fever | 85.7 | 4.8 | 43.6 | 70.9 |

Any nurse could study out the above White House Report figures and put alongside them the figures for her own state.

Fourth, what control measures are commonly used?

A good method by which to classify tuberculosis cases is to divide them into four groups: active, arrested, contacts of known cases, suspects. It is well then to concentrate on the active cases with a close check-up of their contacts.

The public health nurse's greatest contribution in the control of diphtheria is the lesson she causes to sink in as to the need of immunization.

The nurse can do little in whooping cough control without the coöperation of the family and teachers. Teaching the dangers of this disease to the infant and the preschool child and providing for the isolation of this group are her most important tasks here.

Probably education to rule out the mistaken idea that measles is a mild disease is the nurse's strongest weapon.

In the matter of typhoid fever, not immunization but sanitation and the control of the carrier are the means of prevention.

Education with no judgment as to the moral issue is the nurse's cue in

syphilis. Some educational plan should be part of every clinic service.

In scarlet fever, isolation and the complications caused by the disease are the nurse's main teaching points.

Smallpox causes very few deaths nowadays, but this would not be the case if there were no continuous plan for vaccination of the young, which the nurse must always keep foremost in her mind.—Frances F. Hegar, *The Nurse in Communicable Disease*—Paper read at Annual Conference of Health Workers in Tennessee, Fall of 1932.

The Summer Round Up Is a Great Opportunity for Public Health Nurses—In 1925 the Summer Round Up idea of the National Congress of Parents and Teachers was launched, and now it is quite generally recognized as one of the most constructive projects for the promotion of child health. In 1925, 52 associations in 22 states carried through the Round Up compared with 2,739 associations in 47 states in 1931. At first the primary interest in the Round Up was in the physical health only of the children entering school for the first time in the fall; now the attending physician also gives attention to the child's mental health. No longer is the value of the Round Up considered to depend upon the defects discovered or corrected, but rather on the number of parents who have assumed the responsibility for the health of their children.

Here are some contributions public health nurses can make to insure successful Round Ups in their communities:

1. Be a member of a Round Up Committee and see that the proper contacts are made with the medical and dental professions.

2. Be free to assist the examining physicians in their group examinations, insisting that each physician be given enough time to go over each child thoroughly and discuss his findings with the mother.

3. Serve as chairman of the follow-up committee. As such she can instruct the lay group in the most effective methods of making home calls. It is the follow-up work which largely determines the success of the Round Up.

4. The nurse is the best one to make the fall check up when the children bring in their signed slips.—

Lillian R. Smith, M.D., Progress of the Summer Round Up, *Pub. Health Nurs.*, XXV, 2:92-94 (Feb.), 1933.

School Nurses Can Use This—"Guidance Leaflet No. 15," U. S. Government Printing Office, Washington, D. C.—price 5¢—is on nursing and is endorsed by the National League of

Nursing Education. It is a "leaflet of a series on college counseling and advising for the professions; what the occupations are; what preliminary education is required; where professional training is offered; length of training; student budgets, and selected references. . . . The series is designed for use of high school and college students, orientation classes, guidance classes, guidance committees, counselors, teachers and parents." School nurses who are frequently called upon to advise girls about going into nursing will find this leaflet very valuable.
E. F. M.

EDUCATION AND PUBLICITY*

Both Right and Wrong—The following from M. A. Auerbach, Indiana Tuberculosis Association:

Today I happened to look over the November, 1932, issue and read the paragraph "Syndicated Health Columns." I find that in that you list among the health columnists "Dr." Frank McCoy. I wonder if this is the same Frank McCoy who was exposed by the American Medical Association several years ago. If so, Frank McCoy is not an M.D., nor so far as anyone can learn, is he a doctor in any sense. In the April and August, 1927, issues of *Hygeia* will be found articles on "Misinformation by Dr. Frank McCoy." Perhaps because the November issue of the *American Journal of Public Health* came while we were busy with the Seal Sale I went over it more hurriedly than is my practice, and therefore did not notice this before. Of course, you made no comment regarding "Dr." McCoy, but I think it is usually taken that, including him as you did among the health columnists, many of the readers would consider that his writings and information are approved.

Right: "Dr." McCoy is the Frank McCoy. Wrong: The list was given

as a matter of news, and with the hope that some reader would raise questions. You saved the day.

Child Health Education Memoranda—Several memoranda have been prepared for the busy grade teacher who is not a specialist and who wishes to learn where to turn for sound, easily accessible and inexpensive educational material and advice. The titles listed below are supplied by Social Work Publicity Council, 130 East 22d St., New York. 3 cents each.

"Plays—Health," 2 pp. Sources for securing plays and information about play production.

"Posters in School Health Education." 1 p. Source list; warning against undesirable posters; emphasis upon school-made posters.

"Home-Made or School-Made Posters." 1 p. Free and inexpensive manuals on making posters.

"Addresses for Poster Mounts and Rubber Stamp Letters." 1 p. A variety of materials for use in making posters.

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Evart G. Routzahn, 130 East 22d St., New York, N. Y.

"Books on Marionettes and Puppets." 2 pp. Annotated list of books about them and how to make and produce them.

To readers of the *Journal* outside of Canada and United States: copies of the above memoranda will be sent free without enclosure of postage.

For motion picture information see "Motion Picture Memoranda" in this issue.

Public Health Education—Two papers, in the Feb., 1933, *Journal*, were given at a session which was a high spot in the 1932 program of the Public Health Education Section. "Motivation in Health Education," by Benjamin C. Gruenberg, was presented in everyday language, illustrated with examples from every-day experiences.

"The Psychology of Public Education," by Edward S. Robinson:

My proposal is that we need to face the problem of public intelligence in the same humble spirit in which the man of science faces other complex realms of natural fact. We need not make a mystery of the public mind. We need not overlook such solid information as we actually possess. But we do need to give up over-confidence. You who have the urgent and practical need to make widespread education effective in matters of health may feel that this plea for an attitude of honest ignorance is a council of despair, but I do not intend it as such. I mean merely to indicate my distrust in the rules and tricks of public appeal which you may obtain for the asking from many confident publicists. . . . If widespread health education is to be continued on its present scale, it would pay you to set up, as the public museums have done, an experimental center where objective standards of educational efficiency can replace the hunch of the artist, the poet, and the advertising man.

Are we overlooking a source of inspiration and ideas if we fail to read *Journal of Adult Education*, 60 East 42d St., New York? Health education is seldom mentioned, but that may make it all the more stimulating and useful to those who wish to get out of

the routine of purely professional thinking. Take a chance, send 75 cents for the Jan., 1933, quarterly issue. We wish that all program committees would read "Panel" and "Panel Postscript" which tell of a method for conducting meetings and convention sessions.

Wide Representation at Health Education Institute—The classification which follows shows the connections of those who were registered for the Institute at Washington.

Public health departments: state or province, 11; district, 2; county, 6; city, 13.

Public educational departments: state, 3; county, 1; city, 1.

Other public departments: county, 1.

Private health agencies: national, 6; regional, 2; state, 3; county, 4; city, 23.

College and university, 16.

Insurance, 3.

Railway, 1.

Commercial health education: national, 3; regional, 2; state, 1.

Information not given, 5.

Two Special "Baby" Editions—Tabloid supplements were issued by *Rochester Evening Journal*, Dec. 31, 1932 (12 pages), and *Rochester Democrat and Chronicle*, Jan. 2, 1933 (20 pages). Both were published with the cooperation of Monroe County Medical Society and Rochester Tuberculosis and Health Assn. The advertising seems to meet the standards such organizations would set. The text is varied and looks readable. But one article runs as long as two full columns. We wish that another year it could be possible to test the audience by a group of selected volunteers, using the "Gallup method" well known to newspapers as a method in checking reader interest of newspapers. For samples address Rochester (N. Y.)

Tuberculosis and Health Assn. 10 cents.

DATES AHEAD

April 23-30, 1933—"Better Homes Week." Address: Better Homes In America, 1653 Pennsylvania Ave., Washington, D. C.

May 1, 1933—May Day and Child Health Day. Address: American Child Health Assn., 450 7th Ave., New York.

June 26-30, 1933, at Toronto, subjects of interest to readers of this department will appear on the program of the National Tuberculosis Association. In the Sociological Section: "The Philosophy of Health Education," by Prof. Ira V. Hiscock; "Authenticity of Health Education Materials," by Dr. W. W. Bauer; "The Tools of the Health Educator," by Dr. Grant Fleming. "Training and Placement of Personnel" in Administrative Section: "Qualifications," by George J. Nelbach; "Training, Recruiting and Staff Education," by Philip P. Jacobs. The National Conference of Tuberculosis Secretaries will consider "Some Essentials of Good Management in a Tuberculosis Association," with 8 sub-topics by as many speakers, this being one of three parts in a single morning session. This will hardly give time for satisfactory discussion and sharing of experiences. Copies of program from National Tuberculosis Assn., 450 7th Ave., New York.

DEPRESSION

"Morale: The Mental Hygiene of Unemployment," by G. K. Pratt, M.D. National Committee for Mental Hygiene, 450 7th Ave., New York. 64 p. 25 cents; 10 at 20 cents; 50 at 15 cents; 100 at 10 cents. Unemployment relief workers, social workers, public health nurses, clergymen, educators—all who must look into the anxious faces of the unemployed—will find this an invaluable aid. It seems

possible that many men's clubs, women's clubs, and other groups might find material in the pamphlet for a meeting program. Staff conferences and groups of health and social workers might use the material for discussion."

Valuable material for meeting budget depression efforts is contained in *Health News*, Los Angeles County Tuberculosis and Health Assn., 132 W. 1st St., Los Angeles, Calif. May-June, 1932. "Cost of Preventable Sickness Far More Than Public Health Cost," and "What Price Health?" by Health Officer Pomeroy; and "Public Health Returns Dividends of 600 Per Cent in Eleven Years" could be quoted or adapted. "What Price Health?" pictures some health protection contacts experienced by "Mr. Citizen" in the course of his average day. In a cover-page box is a "Statement—Bank of Public Health in Account With Los Angeles County Taxpayers," with total "Expenditures" and "Savings."

"Mental Relief for the Unemployed," by Troyer and Clapp, tells of an experiment in opening regular college classes to qualified unemployed people of Appleton, Wis. The analysis of the whole experiment suggests the possibility of courses in personal and community hygiene for popular education and "mental relief." We hope that some readers who have been interested in exploring adult group work in health education will give serious attention to this article. In *Journal of Adult Education*, 60 East 42d St., New York. Jan., 1933. 75 cents.

"The Economic Depression and Public Health." *Quarterly Bulletin*, Health Organization, League of Nations, Geneva. Sept., 1932. "Mortality and Morbidity Statistics"; "The Nutrition of the Unemployed"; "Indications of a Reaction of Unemployment on Health"; "Psychological Effects of Unemployment." 50 cents. World

Peace Foundation, 40 Mt. Vernon St., Boston.

"Robbing Tomorrow To Pay for Today." Radio talk given recently for Ohio Public Health Assn., Columbus.

"Unemployment And Health," a radio talk, from Illinois State Dept. of Health, Springfield. *Free*.

EDUCATIONAL MATERIAL

The diverse material listed under this or similar headings from month to month includes reference material as background in preparing popular material; other material which may be secured in quantity or be reproduced for local use; as well as some items to be passed on to key individuals or small selected groups.

A single copy, or several copies, may at the right time be just what is wanted for newspaper editorial use.

Other uses with individuals may mean as big a job accomplished as the distribution of hundreds or thousands of leaflets in mass fashion.

"Cosmetic Follies," by H. Goodman. Reprint from *Hygeia*. Dec., 1932. 4 pp. 5 cents. "Common sense becomes uncommonly good sense when it is applied to the use of cosmetics." If anyone sends copies of this to local "woman's page" editors please report if any use of the material follows.

"If I Keep My Health," by Dr. W. W. Bauer. Reprint from *Hygeia*. Dec., 1932. 3 pp. 5 cents. A conversation about the health inventory. Some health officers could make it into a monologue; others could condense it into a dialogue. Try it on Rotary?

"What Price Antivivisection?" by B. H. Moon. Reprint from *Hygeia*. Nov., 1932. 7 pp. 10 cents.

The above reprints from American Medical Assn., 535 North Dearborn St., Chicago. Lower rates for quantities.

"Household Mechanical Refrigeration, With Special Reference to the

Toxicity of the Refrigerants Utilized." A report and an editorial reprinted from *Journal of A.M.A.*, June 7, 1930. Thought to be of timely interest. A. M. A. 6 cents.

Two issues of "The Little Blue Books" came from the Division of Child Welfare, Dept. of Pensions and National Health, Ottawa, Ontario, in 1932. "Maternal Care" and "Infantile Paralysis." "The Little Blue Books," as written by Dr. Helen Macmurchy, may be counted upon for usable ideas as to what to say and how to say it. They are directed to the interested citizen as well as the person directly concerned. Not everyone will wish to use quite as many capital letters, but that is easy to handle. Two earlier issues received recently are: "Rickets: Prevention and Cure"; and "Keep the Family Well: Protection by Prevention." Specify French or English edition.

"Surveys of the Medical Facilities in Three Representative Southern Counties," by O. S. C. Guild, M.D.; "The Ability to Pay for Medical Care," by L. S. Reed. Two of "Abstract Publication" series of Committee on the Costs of Medical Care, 910 17th St., N. W., Washington, D. C. *Free*.

"Shall We Afford Health," by Mary Ross. *Survey Graphic*, 112 East 19th St., New York. March, 1933. 30 cents. "How the dice are loaded against both those who need and those who give medical care" is brought out in this article, based on two of the Costs of Medical Care publications.

"Some Facts About Malaria." Revised edition of a Farmers' Bulletin. Supt. of Documents, Washington, D. C. 5 cents.

"Education." A revision of the catalogue of government publications. Includes in print titles on health, physical, safety, and sex education. Supt. of Documents, Washington, D. C. *Free*.

"Safe At Home." John Hancock Mutual Life Insurance Co., Boston. 14 p. *Free*. One of the most dangerous places in the world is the modern home. This readable booklet tells how to make home safe for child and adult.

"1932 Supplement to Catalogue." National Dairy Council, 111 North Canal St., Chicago. New material and some discontinued material. *Free*.

"A Study of Sickness Cost and Private Medical Practice," by D. B. Armstrong, M.D. Metropolitan Life Insurance Co., New York. *Free*. A paper read before A.M.A., May 13, 1932.

The provision of valuable pamphlets on professional topics, made available by a manufacturer is illustrated by publications from Medical Division, Eastman Kodak Co., Rochester, N. Y.: "X-Rays and Health"; "X-Rays in Dentistry"; "X-Rays in Medicine." *Free*.

DIPHTHERIA

Saving Children's Lives is a report of the final luncheon of the Diphtheria Prevention Commission of the Department of Health of New York City, 1932. 52 pp. Includes "The Story of the Campaign," "The Example Set by Diphtheria Prevention," "Diphtheria Prevention as a Financial Gain," etc. Does not look like a governmental report, and the interesting typographical arrangement removes all of the dull appearance so characteristic of mere reports of a meeting.

"Preventing Diphtheria in the United States and the Dominion of Canada" is a "summarization of the way in which diphtheria prevention projects are being carried on in various sections." 15 legal size pages. Statements from 29 cities in 21 states and provinces. This material was collected for distribution at the largely attended luncheon on diphtheria prevention held at the Washington meeting of the A.P.H.A. Both

luncheon and memorandum were due to Mrs. Marie F. Kirwan, State Committee on Tuberculosis and Public Health, State Charities Aid Association, 105 East 22d St., New York. Copies *free*.

A 4-page folder on diphtheria from Bureau of Health, Trenton, N. J., is simply and clearly written. Good use is made of black-face headings which lead direct into the subsequent paragraphs.

MOTION PICTURES

A reduction in costs enables the American Social Hygiene Assn., 450 7th Ave., New York, to reduce the price of its 16mm motion pictures. The remainder of 35mm film, inflammable, will be sold at half price.

This description of an amateur picture, from *Movie Makers*, illustrates the possibilities in content and use:

Dr. David Ulmar, in New York City, has completed a 300 foot health film, dramatically showing the necessity for the care of scratches and bruises to prevent infection. The story tells of an accident at a boys' ball game when one of the youngsters, who receives a minor scratch, fails to give it proper care. Later, infection sets in and the injury requires medical attention. This is made the occasion of a brief but effective sequence on the cause and development of infections. The picture was made partly as an object lesson for the boys under medical observation, who took part as actors, and partly as a teaching film for the benefit of other boys' clubs.

"The Production of Animated Diagrams With Amateur Equipment," by R. L. Petry. *Education Screen*, 64 East Lake St., Chicago. Jan., 1933. 25 cents. A simple, practicable method by which an amateur may produce diagrams involving motion; doubtless applicable to production of statistical diagrams.

Movie Makers, 105 West 40th St., New York. Feb., 1933. 35 cents. Includes articles for the amateur on inexpensive home built outfit for trick results, expert counsel in film editing, and interesting ideas as to closeups.

A lot of back numbers of *Movie Makers* are being sold at 15 cents a copy. Every issue contains valuable ideas. Ask for list of available numbers.

"16mm Movies on the Mission Field," by N. B. Bercovitz. *Educational Screen*, 64 East Lake St., Chicago. Dec., 1932. 25 cents. How a Korean hospital produced amateur pictures for such eminently practical lessons as giving baby's bath and a mother feeding a baby. The pictures were shown to as many as 2,000 mothers at a time. The picture was shown, then the nurse described what they had seen, then it was shown again with the speed reduced at points where it was desirable to get full detail.

"Where to Buy, Rent, and Borrow 16mm Films—Silent and With Sound." Victor Animatograph Corporation, Davenport, Iowa. 5th Edition. 64 pages. Free. An attempt to list all sources for all subjects. Includes some information about projection, care of film, etc.

REPORTING

We don't get to see many annual reports of national health agencies and so can make no comparison, but "1932 in Review," by Jean B. Pinney, offers a remarkable array of presentation, interpretation and promotion activities. In this "Summary of Activities of the American Social Hygiene Association" we note especially the material under "Conferences and Conventions," "Popular Health Instruction," "Social Hygiene in the Schools and Colleges," "Parent-Teacher Associations," "The Women's Clubs," several sub-headings under "Routine Activities." Nearly all executives and health workers could read this to the advantage of their own work. In *Journal of Social Hygiene*, 450 7th Ave., New York. Jan., 1933. 35 cents.

The Middletown, N. Y., Health Officer's report is quite as satisfactory this year as last when it won a certificate of merit from the Social Work Publicity Council. In appearance it is a masterly piece of mimeographing, with its neat right margin quite as even as its left and its good-humored illustrations. We marvel at the facial expressiveness of the tiny figures in the sketches that Mildred Dillistin, the skilful mimeographer, draws on the stencil. The copy is readable and well organized. We do find the title, and what we gather is the sub-title, of the report, "The Useful Citizen of Tomorrow Will Be the Child Who is Being Well Cared for Today" a bit unwieldy, but we predict that the sketch of a baby on the cover will draw all attention from that title.—Hilary Campbell.

What one state department, with fairly adequate funds may do in health education, and the reasons for what it does, is set forth in the Biennial Report, 1929-1931, of Tennessee Department of Public Health, Nashville. The chapter on "Health Education" covers 12 pages, including several diagrams and maps. There are the following sub-headings: "School Health Education," "Health Education for the General Public," "Training of Personnel," "Miscellaneous Activities," "Health Education Activities of County Health Departments." The following paragraphs introduce the chapter:

Activities in Health Education Service have covered a very wide field. From a broad general standpoint it might be said that all activities of a health department are in the nature of health education, but aside from this, there are certain specific procedures in the state's program which come under the classification of health education. Essentially these are health education for the school child, health education for the general public, health education for professional personnel, and miscellaneous services.

The budget for health education proved itself insufficient for the conduct of a reason-

ably adequate program. In order to supplement it, aid was obtained from The Commonwealth Fund, so that in addition to the director there could be employed an associate director for general public health education, a portion of the salary for operator of a motion picture truck, and a fund for printing pamphlets and other health educational material.

SCHOOLS AND CHILDREN

Correction: "Safety and Health of the School Child," by J. F. Rogers, was priced at 10 cents in the February *Journal*. Single copies are free; 5 cents each up to 50 copies; 4 cents each in larger lots. U. S. Office of Education, Washington.

Before this paragraph is printed the first issue will appear of *Spyglass*, a quarterly health magazine written for children in the fifth and sixth grades. Address Miss Anne Whitney, American Child Health Association, 450 7th Ave., New York.

In "A Plea for School 'Fads,'" Dr. William H. Kilpatrick urges that in retrenching some of the newest ideas may be worth saving. Said Dr. Kilpatrick:

Health instruction is a new thing. Is it a fad? Shall we cut it out? The figures give the answer. Where people learn better how to live and do it, the death rate comes down. The schools have helped people know better what to eat and how to live. We cannot cut out health instruction.

On the school page, *New York Times*. Sunday, Feb. 5, 1933. Doubtless you may find this in your public or university library.

"Camps and Public Schools," by M. M. Ready. Office of Education, Washington, D. C. 9 pp. Free. Information about camps for normal or malnourished children maintained by or in connection with public schools.

"Children's Dentistry in Honolulu" is the 1932 report of Palama Settlement's Dental Clinic for School Children. A special contribution is the data on unit costs of the service. It was clever to print the envelope in the same tone as the postage paid permit stamp.

From Philip S. Pratt, director of Palama Settlement.

"Lists of judged outstanding health and physical education courses for elementary, junior and senior high school grades," are 4 mimeographed pages listing public school courses of study, with date and grades included. Supplied by Teachers College, Columbia University, New York. Useful if one wishes to select from the shelves of the school library. Some of the courses may be available—probably at a price. Send 10 cents for the lists.

"Helpful References on the School Lunch," under "Nutrition Information," by M. B. Bakkie. *Red Cross Courier*, Washington, D. C. Jan., 1933. Sample free. Information sources for rural and city schools.

"High Spots in School Health," by J. F. Rogers, M.D. Reprint from *School Life* 2 pp. Biennial Review, 1930-1932. Address the author, Office of Education, Washington, D. C. Free.

The monthly calendar of special topics covered by *School Health* runs as follows: October—Ventilation and Cold Prevention; November—Nutrition—Teeth; December—Posture and Exercise; January—Health Examinations; February—Sleep, Rest and Eyes; March—Mental Hygiene and Character Education; April—Tuberculosis—Communicable Disease; May—Play Days and May Days. Vacations.—Detroit Tuberculosis and Health Society.

"The Rural Hot Lunch as a Health and Social Activity," by Mary G. McCormick. State Education Department, Albany, N. Y. 19 pp. Free to teachers in New York; 10 cents to others. Dietary hints in addition to "An Activity That Promotes Good Health Habits" and "Health and Social Activities for the Noon Hour."

"What Is Your School Room Temperature?" A blank form for hourly

record for a week; "too hot" and "too cold" indicated; with paragraphs on heat and moisture.

"My Graph of Height, Weight and Growth." Includes weight record spaces for a year.

Both of the above are laid out so that the facts may be emphasized as a graph. Both from Minnesota Public Health Assn., 11 West Summit Ave., St. Paul, Minn. Enclose 3 cents for samples.

RURAL WORK

"Improvising Equipment for Home Hygiene Classes," by Alice Adshead. *Red Cross Courier*, Washington, D. C. Jan., 1933. *Sample free.*

"Friend Hectograph," by Gertrude Spaulding, under "Public Health Nursing and Home Hygiene Service." *Red Cross Courier*, Washington, D. C. Jan., 1933. How a rural Red Cross nurse uses the hectograph in duplicating material for reaching 60 teachers in 43 schools in a county. *Sample copy free.*

THESE HAVE BEEN BROADCAST

Upon request to the sponsors copies of most of the radio talks listed below will be supplied to health agencies.

American Child Health Assn., 450 7th Ave., New York: "Straight As an Indian," "Out of the Ordinary Children."

Baltimore City Health Department: "The Will to Win" (President Roosevelt), "Your Very Young Child."

Connecticut State Dept. of Health, Hartford: "The Health Inventory," "How Much Do You Spend for Health?" "Safeguarding the Adult Teeth," "Teaching the New Mother to Care for Her Baby," "What Do You Know About Your School Water Supply," "The Work a Health Laboratory Does."

Jefferson County Board of Health, Birmingham, Ala: "Fighting Our

Greatest Enemy" (tuberculosis).

Massachusetts Dept. of Public Health, Boston: "Hemorrhagic Diseases," "Insurance Against Diphtheria," "What Is New in Infant Feeding?" "Cancer," "The Heart," "Your Title to a Job," "Why a Health Department?" "Effects of Fatigue," "Vacation Health," "The Use and Abuse of Serums and Vaccines," "Can We Prevent Diabetes?" "Hobbies and Health."

New Hampshire State Board of Health, Concord: "Child Care—One to Six."

New York State Department of Health, Albany: "Rickets," "Social Hygiene," "Food for Health," "Quarantine and Isolation of Persons Affected With Communicable Disease," "Preventive Dentistry," "Baby Teeth and Their Care" "Shopping for Milk."

State Department of Public Health, Springfield, Ill.: "The Heart, the Arteries and Blood Pressure," "Advantages of Winter Vacations," "New Ways to Combat Rickets," "Public Welfare and Public Health," "Diabetes, a Growing Health Problem," "The Disease Carrier," "Milk and Health."

Please send in copies of broadcasts not in the form of talks.

CRITICISM

"The most recent atrocity perpetrated by that form of art called the motion picture business is a picture called 'Life Begins,'" says *Journal of A.M.A.*, Chicago. A weird presentation of maternity hospital conditions. See issue for Nov. 19, 1932, for details.

Health and Welfare groups wishing to discuss criticisms and how to handle them may secure an outline for one or two sessions entitled "When We Are Criticized." Send 3 cents to Social Work Publicity Council, 130 East 22d St., New York.

BOOKS AND REPORTS

Life Begins at Forty—By *Walter B. Pitkin*. New York: McGraw-Hill, 1932. 175 pp. Price, \$1.50.

Modern youth, we are told by this professor of journalism, is in the red. Fools die young. The whole system of education is wrong. Life really begins at the age of forty and everything great is achieved after that time.

Such is the thesis of this little book and it must be admitted that the author argues his case skilfully and at times plausibly, even if his conclusions are based upon somewhat tenuous facts. The physiological and psychological data employed are not always strictly in accord with the latest scientific principles, but a certain latitude in their interpretation is probably allowable.

The book will prove interesting and inspiring to most individuals who have reached or passed the fourth decade of life, but somewhat discouraging to callow youth. The typography is good, the paper not so good, and there is no index.

JAMES A. TOBEY

Social Hygiene in Schools. *Report of the Sub-committee on Social Hygiene in Schools of the White House Conference on Child Health and Protection*—William F. Snow, Chairman. New York: Century, 1932. 59 pp. Price, \$.50.

The importance of social hygiene cannot be overstressed in the present unsettled state of affairs. This report from the White House Conference is well conceived and is written with a balance and insight which is highly commendable.

Part I considers briefly, but clearly, the problems, principles, and methods of social hygiene. The primary aim of social hygiene is stated to be "the preservation of the family and the

improvement and enrichment of family life." It "confines itself in the main to the group of personal and social problems which grow out of the mating instinct. . . . The essential task of social hygiene is to harmonize this conflict as far as possible, by directing the individual's sex nature so that it may contribute most richly to his self-development and happiness and at the same time conserve and advance the welfare of society." An excellent statement is given of the established facts and principles of social hygiene.

Part II treats of the functions of homes, schools, and other social agencies in meeting the problems. These are taken up systematically for infancy, childhood, and adolescence. Perhaps the most telling part of this report is that dealing with adolescence. It seems to focus the whole problem.

Parts III and IV sketch in mere outline certain supplementary community activities and indicate lines for further study and research. A carefully selected, working bibliography completes the report. The report should prove useful in the hands of parent-teacher groups, social workers, and educators.

RICHARD A. BOLT

Community Health Organization—*Edited by Ira V. Hiscock*. New York: The Commonwealth Fund, 1932. 261 pp. Price, \$2.50.

This valuable manual of health administration is the result of 12 years' experience on the part of the Committee on Administrative Practice of the American Public Health Association. Professor Hiscock, the editor, in collaboration with the members of the committee, after a critical review of procedures in some 200 American cities, has made available a splendid basic out-

line for the health services of a modern city. What is more, he has given from his store of knowledge much wise comment on problems of organization and coördination of official, professional, institutional, and voluntary health agencies. An abundance of quotations and footnote references add greatly to the usefulness of the volume.

All the usual public health services are described. The text follows rather closely the standards established in the *Appraisal Form for City Health Work*. These standards are now widely accepted. Some may question such items as the quota set for communicable disease hospital bed capacity or the inference that mass efforts to Schick test children after diphtheria prevention are warranted. The volume, on the other hand, affords excellent guidance in the puzzling problems of school hygiene and city housekeeping or environmental sanitation. Industrial and mental hygiene are also considered among the newer aspects of community health administration.

In a courageous way an attempt is made to indicate necessary budget appropriations for the various essential health activities. This courage is reflected in the closing sentence of the volume: "... every dollar spent along the lines laid down will bring ample returns in the strengthening of the vital force and the economic resources of the community."

It is true that during the golden decade ending in 1929 official health budgets were gradually increasing. At present attention is being focused on the question of quality as well as of quantity of health service rendered for the dollar expended. It is being asked in health as in education whether or not government may be doing for the people many things that it should do for itself. Present economic conditions render the whole problem doubly vexatious. There is often a heavy tax burden which

brings a reduced civic budget, while simultaneously large groups are no longer able to finance their own health protection as they did formerly. In general it is believed, however, that health appropriations have never been excessive.

Community Health Organization has already begun to serve as a valuable instrument in the hands of official and voluntary health workers. There are many who will welcome the assistance of Professor Hiscock and the committee as rendered in the volume under consideration. HUNTINGTON WILLIAMS

Outwitting Our Nerves—By Josephine A. Jackson and Helen M. Salisbury. 2nd ed. New York: Century, 1932. 417 pp. Price, \$2.50.

This book was originally published in 1921 and has since been a best seller. A quantity of new interesting material has been added, and the work as it now stands is probably one of the best things of its kind ever presented to the lay reader. It fearlessly raises the standard of sane and scientific hygiene against the cranks and faddists who occupy the half-world surrounding the general medical field. The authors dwell much upon the power of unconscious autosuggestion which is seen governing the public mind in many more ways than is generally realized. They show conclusively that the advertising pages of popular magazines and newspapers, the notices in street cars and subways, and, above all, the tempting counters of the drug store, present a continuous series of ill-health suggestions in one form or another, and the ills that follow from them, being of a purely psychological character, do not yield to ordinary medical treatment, and are to be overcome by freeing the victim from the false suggestion.

Many popular bogeys receive their death-blow in these pages. "That tired feeling" is shown to be largely a

matter of habit and autosuggestion. Here they quote William James at his best with great effect. The current nonsense about internal baths with expensive apparatus is thoroughly exposed, and the popular specter of constipation put where it belongs. The reader is shown in the most convincing way that these functions are, except in certain rare cases, just a matter of mental habit. In fact, the doctrine of mind over matter is the leitmotiv of the book.

Regular habits, a cheerful tone of mind, moderation in all things—these are the principles inculcated. The plea for an all round, well balanced diet as opposed to the counting-the-calories craze is very timely and encouraging.

The new psychology is not overlooked, and, without riding the complex horse to death, or championing either Freud or Jung, they state the general position and the obvious morals to be drawn from it, with characteristically balanced judgment and breadth of outlook.

No better book could be imagined for medical practitioners to place in the hands of any patient. It is brightly written, and completely fool-proof. *Outwitting our Nerves* is worth every cent of the \$2.50 charged for it, but from the point of view of public interest we look forward to the time when it can be placed within general reach at \$1.00.

EMMET FOX

The Sciences of Man in the Making:

An Orientation Book—By Edwin A. Kirkpatrick. New York: Harcourt, Brace, 1932. 386 pp. Price, \$4.00.

This book is intended to give the average educated reader a preliminary orientation into the various sciences dealing with man. It starts out with a discussion of the nature and methods of science and considers under fifteen different chapters such subjects as: Evolution, Anthropology, Physiology, Eu-

genics, Economics, Political Science, Psychology, Education, Religion, Morals, and Ethics.

The book is written in a very clear, non-technical manner. The facts as presented seem to be logically grouped and presented. The attempt to cover such a wide range of subjects obviously means that comparatively little material is presented for any single subject.

An interesting addition to the book is a series of selected researches which appear at the end of each chapter, and which either quote directly or summarize an important piece of research pertaining to the material discussed under that chapter. These seem to be quite well chosen and presented.

There is a list of suggested reading at the end of each chapter to encourage further study of the subject.

On the whole the book appears to fulfil in a satisfactory manner the function for which it was written, and be recommended for that purpose.

KARL M. BOWMAN

Housing and the Community—

Home Repair and Remodeling—*Reports of the Committees on Housing and the Community; and Reconditioning, Remodeling and Modernizing, The President's Conference on Home Building and Home Ownership, Washington, D. C., 1932.* 291 pp. Price, \$1.15.

This volume from the President's Conference on Home Building and Home Ownership is divided into two major portions, namely, housing in the community, and home repair and remodeling. The section on housing in the community discusses such important matters as the relation between housing and health, delinquency, safety, citizenship, recreation, and education. The report is closed with recommendations to the effect that city planning and zoning boards should bend every effort to eliminate blighted areas in the cities

and towns of the United States; that planning commissions should lay out definite master plans for inhabited areas; that secondary blighted areas be reconditioned to prevent further development of slums; that a model act be formulated to serve as a basis for legislation making possible the assembly of land tracts in sufficient size to permit neighborhood community development; that instruction in the essentials of good housing be given in the school system; and that consideration be given in housing plans to such factors as beauty of land layout and recreational facilities.

The second section of the report discusses in much detail the reconditioning, repair and remodeling of the home. Certain recommendations are also given, one of the most important of which suggests that an organization be established qualified to carry out the findings of this committee. In the appendix to this report there is a home inspection check-list which seems to cover every item of the home to which one's attention should be given when considering repairs or remodeling.

ARTHUR P. MILLER

Your Teeth and Their Care: A simple explanation of dentistry, dental procedures, and the relation of the dentist to the public—By Carl W. Adams, D.D.S. St. Louis: Mosby, 1932. 141 pp. Price, \$1.25.

This helpful little book is the outgrowth of a number of questions which have come to a busy dentist. Over a number of years, he presents in concise form the answers to questions concerning the structure and function of the teeth, their irregularities, diseases, and treatment. A considerable portion of the book is devoted to oral prophylaxis and the relation of diet to oral health. The chapter on diet has drawn largely from the work of McCollum and Simmonds and from Dr. W. D. Sansum's *Normal Diet*. Dr. Adams takes the

reader into his confidence in the various procedures incidental to dental practice.

In closing this treatise I venture to hope that what I have written will impress upon the reader the importance of preventive dentistry, the aims of which may be summed up as follows: First, to make it possible for every child to be well born, in other words to have a normal set of teeth. Second, to preserve them in health by prescribing a healthful diet. Third, to instruct people how to keep their mouths and teeth clean. Fourth, to impress upon the public the necessity for availing themselves of dental services at regular intervals.

RICHARD A. BOLT

Health Education Activities—By Kathleen Wilkinson Wooten. New York: National Tuberculosis Association, 1932. 288 pp. Price, \$0.75.

This really useful book is planned to meet the needs of pupils of different age and experience levels, namely primary, intermediate, and high school, the latter including both the junior and senior. Each section is preceded by a brief introduction which discusses the general characteristics and interests of the age group and gives definite references for further reading.

The succeeding pages are devoted to suggested activities, the first and most important of which are the surveys for determining health assets and indicating health needs, both for the school environment and the individual pupils. Two sets of survey questions appear in the appendix, and one might regret that the body of the text did not treat in more detail this excellent method of approach to school health problems. Fortunately it does gain emphasis by having the brief paragraph repeated in connection with the activities for each grade and by suggesting the desirability of having older pupils participate in making such surveys.

The second suggested activity, daily health inspection, is also repeated for each grade and early in the primary section introduces the important prob-

lems of individual pupil responsibility and communicable disease control.

The bulk of the volume is devoted to suggested activities and stories which might be helpful to the teacher in establishing desirable health interests or attitudes and in encouraging satisfactory health practices. When the latter concern home practices such as sleep one wishes that it might be possible to guard against the tragedies that sometimes occur because of lack of sympathetic understanding of pupil problems.

For the most part the primary and intermediate materials are carefully graded and interesting, though some of us may doubt the value of home nursing in grade IV, and some of us may be convinced that the very obvious morals of some of the health stories will result in fiendish glee rather than interest in desirable conformity.

The unit of activities for the high school health program is not a result of the author's experience but it represents what has been done successfully in a number of high schools throughout the country and should be a valuable reference for all high school administrators and teachers who are, or wish to be, convinced that even the teen age can recognize the importance of health for happy and successful living.

MARY L. HAHN

Cultivating the Child's Appetite—

By Charles Anderson Aldrich, M.D.
2d ed. New York: Macmillan,
1932. 137 pp. Price, \$1.25.

Modern parents have accepted whole-heartedly the idea that their child must eat certain foods and certain quantities thereof to be healthy. They make necessary sacrifices to secure the right kinds of foods, and study assiduously the advice of nutrition experts; but many of them strike a rock when they face the will of the child whom they are trying to feed. The complaint that,

"I cannot make my child eat what he should," is common.

To such parents Dr. Aldrich's book will be a real boon. It presents in simple form the principles which control appetite, but will perhaps be more highly regarded by the parents for the sympathetic way in which he discusses their problems in controlling the psychology of the child. There is probably no single set of directions that will ever answer the question of how to make any child eat what it should, but Dr. Aldrich has gone far in providing helpful suggestions in the solution of this problem.

W. H. EDDY

Reports, National Quarantine Service. Series II—1931—*By Wu Lien-Teh and Wu Chang-Yao.*

This publication reviews quarantine practice in China before the National Quarantine Service took over the control of port health work at Shanghai from the Chinese Maritime Customs on July 1, 1930, and gives a complete history of the development of the National Quarantine Service since that date.

The history of modern quarantine practice in China dates back to the year 1873 when measures were taken at Shanghai and Amoy against the threatening invasion of cholera from Siam and the Malay Peninsula. The initiative at Shanghai with regard to quarantine was taken by the Commissioner of Customs and in 1874 the first comprehensive quarantine rules ever adopted in China were issued. These rules were approved also by the Treaty Power Consuls. These were followed from time to time by the adoption of similar rules at other Chinese ports. These regulations, however, were difficult of enforcement, principally because of lack of the necessary quarantine facilities for this purpose.

By an arrangement with the Ministry of Finance, which controls the Customs,

the port health work at Shanghai was taken over on July 1, 1930, and put under the authority of the Ministry of Health, acting through its National Quarantine Service. Since that date several other ports, i.e., Newchwang, Amoy, Swatow, Antung, and Hankow have come under the control of the National Quarantine Service.

Preparatory to the transfer of the port health work from the administrative jurisdiction of the Customs Administration to the National Quarantine Service, an extended tour of instruction was made by various officers of the National Quarantine Service. This tour was undertaken with the object of studying the latest developments in port sanitation and allied subjects in the principal ports of Europe, United States, and Asia and was conducted under the joint auspices of the Health Section of the League of Nations and the Nationalist Government of China.

Benefiting by the knowledge gained on these tours, the National Quarantine Service adopted the new quarantine regulations recommended by Dr. C. L. Park, Director of the Australian Quarantine Service and Chief of the Epidemiological Division of the Health Section of the League of Nations, who made a survey of the quarantine needs at Chinese ports under the auspices of the League of Nations, which included the most modern quarantine practices and were promulgated in English as well as in Chinese text.

With the object of increasing the efficiency of the Service, the headquarters of the National Quarantine Service at Shanghai has been organized into four main divisions: Administrative, Boarding, Fumigation, and Medical Service, under division heads which were in turn responsible to the Director. A special department of investigation and research was instituted in December, 1930, and under its direction a rat and flea survey of the port

of Shanghai, and laboratory research in the cholera problem are being carried out.

Detailed reports of the various divisions for the year 1931 are contained in this publication and much other valuable information is gleaned therefrom with respect to recently instituted quarantine practices and improvements at the various ports in China.

That an improvement in the quarantine service of China has been made is suggested by the control and early suppression of the cholera epidemic which broke out in Shanghai in the summer of 1931 when 482 cases with 57 deaths were reported and which was suppressed in 76 days from the discovery of the first case.

F. A. CARMELIA

The History of Dermatology—By William Allen Pusey, M.D. Springfield, Ill.: Charles C. Thomas, 1933. Price, \$3.00.

The author states in his preface that there is no history of dermatology in English, and has undertaken to supply this need. Everyone knows that there is no one better fitted to write such a book than Dr. Pusey. Not only does he know his subject, but he knows how to write in an interesting and orderly manner.

The book begins with ancient dermatology, Egypt to Greece, 3000 to 300 B.C. It brings us down through Graeco-Roman, Arabian and medieval dermatology, Rome to the Renaissance, 300 B.C. to 1500 A.D., and so on to the present. Dermatology began to find itself, so to speak, 1750 to 1825, clinical and laboratory dermatology 1800 to 1850. The first phase of modern dermatology in Continental Europe and in Great Britain and the United States is placed from 1850 to 1900.

The author, while giving full credit to those anatomists who studied the

skin, the sweat glands, etc., gives to Astruc credit as the true founder of modern dermatology. British dermatology is credited chiefly to Willan (1757-1812), but it is recognized that the founder of French dermatology, Lorry, of Paris, was the first to regard the skin as a living organ of the body with relationships to all other parts. The efforts of Lorry and Willan therefore combined to start the modern stream of dermatology.

Most interesting sketches are given of many of the great dermatologists. The first dermatological society in the world was founded in New York in 1869, and has had a continuous existence to the present. Dermatology in America derived its inspiration from Europe, and James C. White, a disciple of Hebra, is described as being the strongest force in shaping its early course. The author states that spirotrichosis and tularemia are the two diseases which have been discovered and completely worked out in the United States.

A very useful part of the book is a historical index of dermatology, written largely by Dr. Herbert Rattner. The text is well illustrated with photographs of the majority of the men who have been prominent in this line. A good index adds greatly to the value of the book. The printing and make-up are characteristic of the fine work to which we have been accustomed from Charles C. Thomas. MAZŮCK P. RAVENEL

The Diagnosis and Treatment of Postural Defects—By *Winthrop Morgan Phelps, M.D., and Robert J. H. Kiphuth. Springfield, Ill.: Charles C. Thomas, 1932. Price, \$4.00.*

This book should be a valuable addition to the library of any one having any connection with posture work. It should be of particular interest to the school or public health physician and

nurse because of the concise explanations of normal and abnormal positions and subsequent suggestions for treatment.

The book is generously illustrated with photographs and diagrams, with accompanying short, excellently worded explanations. The exercises are especially valuable, since no extra or expensive equipment is necessary. Several of them, which are new to the reviewer, appear to be of real value. The language used throughout the entire book is so simple and well chosen that nurses and physiotherapists who have read it readily appreciate the problems presented, and undertake their correction with a much clearer conception than they had previously.

The work is open to criticism because of the brevity of the first part, dealing with the causes of poor posture, but since it is not intended as an exhaustive treatise on this subject, this adverse criticism cannot be severe.

The make-up and printing are excellent and the reviewer can recommend it for the purposes for which it was intended. WILLIAM J. STEWART

Manual of Microbiology—By *Walter L. Obold, M.S., and Margaret M. Diehm, Ph.D. Philadelphia: Davis, 1932. 140 pp. Price, \$1.25.*

This book is an attempt to present in a very elementary manner a combination of laboratory guide and textbook. While it is primarily a laboratory manual, much material is given which rightfully belongs only in a textbook. This attempt to combine the two is not commendable, since the laboratory manual suffers from the inclusion of textbook material and the subject matter given is not sufficient for a textbook.

Some inaccuracies are noted: The definition of the word "antiseptic" on page 100 gives only the inhibitory meaning. "Phenol coefficient" is

described as a comparison of "the germicidal property of an unknown disinfectant with a standard 5 per cent phenol solution," whereas a phenol coefficient is a figure which represents a comparison of the germicidal efficiency of a germicide with *pure phenol* against a specific organism.

On page 101 it is stated that "*Staphylococcus aureus* should survive a 1 to 70 dilution of 5 per cent phenol for 10 minutes . . .," whereas the statement should read "*Staphylococcus aureus* should survive a 1 to 70 dilution of pure phenol for 15 minutes. . . ." A model table showing the supposed resistance of *Staph. aureus* to phenol is given on page 101 in which it is shown that a 1 to 70 dilution of 5 per cent phenol (which is actually a 1 to 1,400 dilution of pure phenol) does kill in 10 minutes, whereas the statement above indicated that it must not kill in 10 minutes. Such inaccuracies and inconsistencies are deplorable.

The question arises as to where such an elementary manual could be used. It would not find a place in any professional school.

GEORGE F. REDDISH

Public Health and the Private Medical Practitioner—*Compiled by J. L. Pomeroy, M.D., Los Angeles County Health Officer, 1932.*

This document of more than 300 sheets of mimeographed pages, consists of a series of letters, reports and other data related to the operation of the Los Angeles County Health Centers and their relation to the medical practitioners of that county. As a record of successful operation over a period of years, not altogether connected but indicative of the mass of difficult problems that any health center is bound to encounter in its medical relations, this is one of the most human documents that has come to our notice.

While we wish that Dr. Pomeroy had taken all this material and boiled it down into a concise but comprehensive summary of 60 or 80 printed pages, there is much to say in favor of this unique compilation of data, since he gives not merely the impressions of one man as to what a health center might or might not be, but presents also a series of documents to support his impressions.

A few quotations from various parts of the volume are pertinent in giving some of the salient features of the entire report. The following paragraph gives a good definition of the health center program.

The health center program, as applied in Los Angeles County, is based upon an action by the Board of Supervisors of the County of Los Angeles, whereby they have set up a Medical Advisory Board to act with the Health Officer of Los Angeles County in the administration of health centers in various localities of Los Angeles County with a population of approximately 100,000, the cost of these health centers to be borne both by the community in which they are placed and by the County of Los Angeles. The cost to the community is usually covered by a contract between the city and the Board of Supervisors of Los Angeles County. A constitution and by-laws has been prepared which details the purpose, the membership, the organization, the duties of the staff, the meetings of the staff, the recommendations of each individual health center. These are known as a constitution and by-laws of the medical staff of the particular district health center. This constitution and by-laws can be amended by a two-thirds vote of the attending staff, provided that the said amendment shall first be submitted in writing to the Medical Advisory Board of the Los Angeles County Health Department.

The Health Centers in Los Angeles County naturally encountered a number of difficulties and criticisms which are summed up in one of the reports.

These various criticisms are carefully discussed. Because of lack of facilities, particularly in emergency social work, the health centers were found to be treating cases that might

well be cared for by private physicians. Nevertheless, while not entirely approving some of the procedures of the health centers, the committee was of the opinion that it was the duty of the medical organizations and the private practitioners of medicine to support these health centers.

Another quotation giving an unusually fine statement of the relationship of a private practitioner of medicine to public health in general is:

It is the duty of every physician, whether he be public health officer or whether he be a private practitioner, to stand back of and uphold public health principles in our communities. Public health is a product of the private practitioner, and it is necessary that its tenets be upheld by the private practitioner.

After going through these pages, one gets the impression that while the health centers and the department of health have been criticised, on the whole, organized medicine in Los Angeles County is decidedly favorable to public health work.

PHILIP P. JACOBS

Benzol (Benzene) Poisoning. *A new investigation of the toxicity of Benzene and Benzene impurities—By Carey P. McCord in collaboration with Nora Cox and Charlotte O'Boyle. The Industrial Health Conservancy Laboratories, Cincinnati, Ohio. 2d ed. 1932.*

The purpose of the present volume is twofold: to present certain newer evidence concerning the toxicity of highly purified benzol and of certain of the impurities found in commercial benzol, and to provide the medical practitioner with a review of the present-day knowledge of benzene poisoning.

In the studies on various grades of benzenes, absorption of these substances was brought about by inhalation, the test animals being guinea pigs and rabbits. The concentrations used

were 500 and 1,000 p.p.m. of air, usually for a period of 7 hours daily. These studies disclosed all of the various types of benzol to be capable of producing poisoning in the test animals.

Studies on skin absorption of benzol were conducted on 10 rabbits. The smallest dose, applied to the clipped skin of the trunk was 4.2 c.c. daily, while the largest dose was 15 c.c. three times daily. All of the 10 animals died within 11 days. Damage of the skin brought about by the wrappings used to apply the benzol and the benzol itself undoubtedly influenced the nature of the final picture for "at times extensive sloughing took place." The author concludes that "benzol in contact with the skin, in addition to causing a dermatitis or kindred skin lesion, is capable of producing systemic poisoning."

The studies of the toxicity of the impurities of benzene were confined to a study, by inhalation, of acetonitrile, thiophene, amylene, methyl disulphide and carbon bisulphide. Again rabbits were used as the test animal and the substances, as before, were administered by inhalation. These studies according to the author do "not provide any evidence tending to place the burden of benzene toxicity upon its impurities."

The second objective of this study, namely the provision of an adequate review of the subject of benzene poisoning for the guidance of the medical practitioner, is certainly very well achieved. The symptomatology of benzene poisoning, the medico legal aspects of the disease, its treatment and the protection against benzene are well presented. Certainly those persons interested in the medical aspects of this subject will find this portion of the monograph of value. The volume is replete with references to the literature and the terminal bibliography is a reference source of real value in this field.

LEONARD GREENBURG

Ethics in Nursing—By Gene Harrison, St. Louis: Mosby, 154 pp. Price, \$1.50.

The author states that this volume on ethics is meant for the modern nurse who does her own thinking in a nursing school where the old militaristic type of etiquette is no longer in vogue. Yet somehow the author's tone gives one the impression that she trained and taught and had most of her experience in a militaristic type of school. There are too many must's and should's, too much formality.

There is a general introduction with many explanations more or less concrete of what ethics is, how it developed and the like. Part I is for the undergraduate, and here one whole chapter is given over to choice of a vocation and of a nursing school, which presumably the nurse has already made and no longer needs.

The second part of the book is for graduates. Here it is a little hard to see why the description of lines of work a nurse may choose after graduation has to do with ethics which is concerned with right and wrong.

The author has stated in clear form the organizations a nurse should belong to when she graduates. Most young graduates are in a muddle as to the difference between belonging to alumnae associations and the district, state, and American Nurses' Association. Many of them think it costs money to enroll in the Red Cross Nursing Service.

Most of the ethical problems of a nurse are dealt with in this book, but one of the greatest ethical problems a nurse has seems to be conspicuously absent—that of her relation to the physician. The word doctor appears but once in the book and that only incidentally. Perhaps ethics in nursing does not include the doctor, but it seems to me the patient may as well be left out as the physician. The public health nurse, for instance, often finds

her medical ethics problems very difficult because she has the patients of not only all the physicians in the community but of every quack as well. Something could be said about the loyalty of private duty and institutional nurses both in word and deed to individual physicians or medical staff.

There are new ideas in the book, and the style is vigorous and individual, but in my opinion better books on ethics for nurses are already on the market.

EVA F. MACDOUGALL

Slums, Large-Scale Housing and Decentralization. *Reports of the Committees on Blighted Areas and Slums, Large-Scale Operations, Business and Housing, Industrial Decentralization and Housing. The President's Conference on Home Building and Home Ownership. Washington, D. C., 1932. Edited by John M. Gries and James Ford.* 245 pp. Price, \$1.15.

It is generally believed that because of their lack of financial resources poor people must live in slums and blighted districts. For some time, however, a group of able minds has been at work on the housing problem for persons of limited means. The present volume presents the results of the deliberations of four sub-committees of President Hoover's Conference on Home Building and House Ownership dealing with this very problem.

The obstacles to slum clearance are many—in fact too many to discuss in detail here. Many of these are of relatively little importance. Two of the greatest obstacles are the lack of legal authority required for slum clearance and the problem of adequate financing arrangements. Both of these important parts of the problem are discussed in a most satisfactory manner in the committee reports. The plan for slum clearance submitted by Mr. Veiller is a model for practical use and alone is

a valuable document on the housing problem. Other portions of the volume deal with large-scale operations, business and housing, and a most valuable discussion of industrial decentralization and housing is presented.

A plea is made for a more widespread application of the new viewpoint in the housing field, the viewpoint of industrial large scale fabrication and assembly. It is interesting to note that this aspect of the problem is receiving the attention of the industrialists. At the forthcoming Chicago exposition such factory-made homes will be on exhibit. Perhaps the present depression is laying the groundwork for the remedy of one of the old social evils.

LEONARD GREENBURG

Principles of Mental Development.

A Textbook in Educational Psychology—By Raymond Holder Wheeler and Francis Theodore Perkins. New York: Crowell, 1932. 529 pp. Price, \$3.75.

This textbook has been written with the purpose of placing the prospective teacher in such a position that the varied problems in the schoolroom and in that part of the community represented in that room may be met in an intelligent and a helpful, guiding spirit.

The teacher can no longer approach his work with an idea of pouring out profusely the store of knowledge and information in his possession irrespective of the needs of the individual pupil.

This book has placed in a readable, intelligible, and helpful manner the recent advances in those subjects bearing upon the education of the child of today. It covers in one volume a vast store of knowledge and practical information which should prove a blessing to the teacher and the one taught.

Each child is entitled to gather the necessary amount of book learning, but far above that is his right to be taught the art of living, and the value of self-

adjustment to his environment. The child should emerge from the educational system as a personality that has acquired a necessary amount of information for present needs—how and where to secure additional information—how properly to assimilate and apply it to his problems. He should have a sound mind in a sound body ready to be of service to himself and to his community.

The authors of this book have recognized three great factors in the educational process and stress these occasionally so that they may not be lost sight of in the great mass of material on this subject. These are:

First—What are the problems always faced by the teacher, as a personality, if adequate instruction is to be given at all times?

Second—How adequate in the light of educational psychology are the various methods of instruction and the machinery of the school system?

Third—What are the merits of educational psychology, itself, as a set of principles by means of which to determine educational machinery, methods, and an understanding of the child?

This text is a step in the right direction and cannot fail to assist the conscientious prospective teacher (as well as the one in the work) to see the work in a new light—a wealth of material is placed at his disposal and should help make him a helpful and an inspiring personality in the great work of preparing human beings for successful living—that great field where each must face life, understand life, and live it.

CHARLES HAMMOND

New Jersey's Agricultural Experiment Station—1880-1930—By C. R. Woodward and E. N. Waller. New Jersey Agricultural Experiment Station, New Brunswick, N. J., 1932. 645 pp. Price, \$2.50.

This volume is necessarily both a history of the development of the Agricultural Experiment Station and a

review of its accomplishments since its inception. The first chapters are devoted to a review of agriculture and agricultural economics in New Jersey, the establishment and the later development of the teaching of agriculture, including the founding of the Experiment Station. Subsequent chapters deal with the subjects taught or in which research was undertaken. Of these latter investigations, the history of the work on the study of the oyster is of most interest to public health workers, much necessary information about this mollusk being obtained by Dr. Julius Nelson and his successors. Resulting from studies undertaken by this station, the present system of mosquito control in New Jersey, particularly of the salt-marsh species, has developed. The station's contributions to dairy husbandry have been noteworthy. Since 1925 research in agricultural biochemistry has added to the knowledge of nutrition, vitamins, diet influences, and so on.

Perhaps the work of most interest to the sanitary and public health engineers is the work carried on by Dr. Willem Rudolfs and his associates, a brief review of the work and facilities available for these studies being given. As pointed out in the beginning, this book is a review of accomplishments. Details are not given, but valuable references are appended.

VINCENT B. LAMOUREUX

Our Wonderland of Bureaucracy—
By James M. Beck, LL.D., Litt.D.
New York: Macmillan, 1932. 272 pp. Price, \$3.00.

In this well written, well printed, and interesting book a former Solicitor General of the United States, now a member of Congress, endeavors to trace the mushroom growth of the many federal bureaus and departments. He quotes with approval an analogy between the typical government bureau and the

protozoa. Both start from humble beginnings but multiply with great rapidity while acting as parasites.

In view of the effective, efficient, and valuable services performed by many of these bureaus, such as for instance, the U. S. Public Health Service, this comparison would seem to be somewhat exaggerated. There is no doubt that the structure of the federal government is top-heavy and unwieldy, and urgently in need of reorganization along more effective lines, but Mr. Beck's indictment of it is at times a trifle overdrawn. To him, for example, the Children's Bureau is anathema, which may or may not be a justifiable attitude.

A book such as this, even if rather hyperbolic, is stimulating reading and should prove of interest and value to sanitarians, most of whom are deeply involved in bureaucracy, usually as participants in this alleged wonderland.

JAMES A. TOBEX

The Fundamentals of Personal Hygiene—
By Walter W. Kreuger.
Philadelphia: Saunders, 1932. 291 pp. Price, \$1.75.

This comparatively brief work is designed as a text in personal hygiene, covering the usual list of topics, such as posture, physical activity, health of the skin, ventilation, nutrition, mental hygiene, and so on.

At the end of each chapter are placed a list of health practices to be acquired, a list of questions for class discussion, and a selected bibliography. This arrangement is to be commended. It seems particularly desirable to have a selected bibliography relating largely to the topics just discussed placed at the end of each section or chapter.

The attempt at brevity results in a somewhat unfortunate situation. In some cases, there seems to be a lack of adequate discussion of basic principles. Too rarely are reasons given for statements made. At the ages for which

this text apparently is designed, reasons must be given if true interest is to be aroused.

The short sentence construction makes the text tiring reading. Interest, therefore, is sustained with difficulty.

In the field of efforts toward establishing healthful living, the present concept tends very definitely toward four things: First, enough basic scientific material so that pupils may understand the reasons for warnings or recommendations; second, a vocabulary that compels students to acquire some knowledge of modern scientific terms; third, a type of statement that will arouse thought and interest; and fourth, a flowing style of discourse that will sustain interest.

The lack of scientific background in the text, the over-simplification of vocabulary, and the short sentences which merely state facts—but rarely give explanations—seem to the reviewer to have produced a text that does not meet the standards set in the preceding paragraph.

CHARLES H. KEENE

Water Analysis for Sanitary and Technical Purposes—By *Herbert B. Stocks*. *Revised and enlarged by W. Gordon Carey*. 2d ed. Philadelphia: Lippincott, 1932. Price, \$3.50.

The original work, published in 1912, described chemical methods of water analyses then in use.

The author has attempted to bring the present edition up to date by the inclusion of a 10-page section on the bacteriological analysis of water. Obviously, in a book of 129 pages of text, this means that the chemical analysis

is stressed almost to the exclusion of bacteriological methods, which are everywhere recognized as being of major importance in the sanitary analysis of water. Methods for the qualitative and quantitative determination of various elements and compounds found in water are given. Eight appendices deal with standards of purity of water, composition of different types of water, aqueous vapor tension, and the preparation of chemical reagents and some bacteriological media.

The printing and make-up are excellent.

NEWELL R. ZIEGLER

Your Teeth: Their Care and Preservation—By *Lewis H. Urling, D.D.S.* Philadelphia: Dorrance, 1932. 67 pp. Price, \$1.50.

Here is another practical handbook written in an easy style for the prospective mother and others interested in mouth hygiene. The author begins logically with the care of the expectant mother and stresses the fact that teeth are formed early during pregnancy. Especial attention is given to diet, including a number of well chosen dietaries. A brief discussion is given of each of the vitamins with their reaction to tooth building. Only a small part of the book is taken up with diseases and abnormal conditions of the teeth and gums. The last chapter consists of a series of "Do's and Don't's About Your Teeth."

"In accepting the author's attempt to present recently discovered knowledge that may be helpful, remember that the desire is only to build upon and not to destroy proven knowledge that has gone before."

RICHARD A. BOLT

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

Medicine for the Next Generation—This contribution is notable for the coinage of "public medicine" (I assume it is original with the author though he doesn't claim it), but it contains many speculations of interest to the sanitarian.

BAKETEL, H. S. The Practice of Medicine in 1950. New York State J. Med. 33, 3:154 (Feb. 1), 1933.

Typhoid Fever in Germany—National boundaries are unknown to water-borne typhoid. This report of experience in Germany parallels ours in the United States.

BRUNS, H. Typhoid Fever Epidemics from Water Supply in Germany. J. Am. W. W. Assn. 25, 1:1 (Jan.), 1933.

Calmette Continues the Argument—As an example of potent pleading, this paper is worth perusal regardless of the merit of its contentions. With more than a million children vaccinated with BCG to testify to its harmlessness, and with continued laboratory studies in every country to test its stability, the author insists that no one has ever really succeeded in rendering BCG virulent, despite the continuing out-pourings of the Doubting Thomases.

CALMETTE, A. The Fixity of the Attenuation of BCG. Am. Rev. Tuberc. 27, 1:1 (Jan.), 1933.

Meeting the Doctor More than Half Way—"The rapid development of public health and its spectacular achievements have created a public demand which the profession of medicine has not yet met," says our Secretary. Public health administration feels this need and urges the practitioner to enter into partnership with "official colleagues in matters calling for ad-

ministrative and engineering skills to which he has not been especially trained."

EMERSON, K. The Practicing Physician and Public Health. South. M. J. 26, 1:31 (Jan.), 1933.

Air for Solons—This description of the system of ventilation for the Senate and Congress halls serves two purposes: it will give aid to the serious student of sanitation and comfort to the humorously inclined.

GREENBURG, L. and BLOOMFIELD, J. J. The New Ventilation Systems of the Senate and House Chambers of the Capitol, Washington, D. C. Pub. Health Rep. 48, 6:137 (Feb. 10), 1933.

For the Beam in Our Own Eyes—At any meeting of health workers, a casual survey will indicate the great need that sanitarians themselves have for the information contained in this excellent article on the care of the hair. Its lessons should be broadcast from the housetops, too.

HAZEN, H. H. and BIASE, F. The Care of the Hair. Am. J. Nurs. 33, 2:123 (Feb.), 1933.

Making Swimming Pools Safe for Swimming—"Since intestinal diseases are spread through the use of swimming pools, only very rarely, if at all, some index of the sanitary quality of the water other than *B. coli* should be employed," conclude these authors who recommend other laboratory checks.

HORWOOD, M. P. *et al.* Indices of the Sanitary Quality of Swimming Pool Water. J. Am. W. W. Assn. 25, 1:124 (Jan.), 1933.

Progress Report in (Mass.) Tuberculosis Prevention—Eight years' experience in the Massachusetts 10-year program indicates a 25 per cent infection with a distinct downward trend. The possibilities in the preven-

tion of childhood tuberculosis are set forth.

LORD, F. T. *The Prevention and Control of Tuberculosis in the Commonwealth of Massachusetts, With Special Reference to Childhood Tuberculosis and the Ten-Year Program.* New Eng. J. Med. 208, 5:248 (Feb. 2), 1933.

What Anti-Vaccinists Do Not Cry For—States with compulsory vaccination laws had 6 cases of small-

pox per 100,000, whereas states where compulsory vaccination is prohibited enjoyed a rate of 115. The states are mapped and listed according to rates with Massachusetts first with 1 per 100,000 and Utah last with 272. Will the computation bother the anti-vaccinist? Not at all!

WOODWARD, S. B. and FEEMSTER, R. F. *The Relation of Smallpox Morbidity to Vaccination Laws.* New Eng. J. Med. 208, 6:317 (Feb. 9), 1933.

MARRIAGE. By Ernest R. Groves. New York: Holt, 1933. 552 pp. Price, \$3.50.

NEWS FROM THE FIELD

MORALE—THE MENTAL HYGIENE OF UNEMPLOYMENT

THE paramount task facing relief workers today is to help the mentally distressed unemployed to preserve their sense of security, menaced, as it is on all sides by the prevailing economic conditions, Dr. George K. Pratt, psychiatrist, declares in a report, *Morale: The Mental Hygiene of Unemployment*, issued by The National Committee for Mental Hygiene, the purpose of which is "to help social workers, unemployment relief investigators and others to understand a little better what goes on in the minds of men and women who lose their jobs."

A very large proportion of the unhealthy mental reactions produced by the depression, Dr. Pratt explains, have their roots in various kinds of insecurities.

While the available statistics do not indicate a general increase in mental diseases serious enough to require hospital treatment, Dr. Pratt reports a great many lesser departures from average mental health and anticipates that "many who have been on the borderline of mental ill health for some time before employment will now go under."

Dr. Pratt points out the job facing every relief and social worker dealing with unemployed individuals as a two-fold one:

Along with the provision of material relief, and as part of this process, is the equally vital task of recognizing early signs of flagging morale and ministering in some measure to the security of the unemployed and their families.

Among the suggestions advanced to the relief worker for the management

of mental health problems arising out of the depression is the following:

When you believe there may be a morale problem involved as well as an acute relief problem, give the unemployed man or woman a chance to talk it out. Psychiatrists have learned that in numerous mental disorders, even when little else can be done by way of treatment, a copious talking out by the patient often results in at least temporary benefit. This process serves to drain off pent-up emotional tension and gives a feeling of relief and relaxation. For a social worker or relief investigator to cultivate deliberately the habit of being a good listener may prove to be half the battle in maintaining a client's morale and mental health.

Nor does the need to release unhappy tensions apply to the program of the social agency alone. Dr. Pratt would have the community also extend wide tolerance to citizens gathered together in groups for the purpose of free speech and public discussion.

Work for its own sake is also recommended as a

... life-saver to flagging morale and to the preservation of self-respect and mental health. "Work for health's sake" is not just a sop to the distracted man who cannot find a paying job. It is a vital need which helps him to maintain a feeling of worthwhileness, self-respect and accomplishment, as well as to keep him in the path toward a wholesome integration of his personality, without which mental health cannot exist. Almost any work will do, as long as it presents a reasonably definite task. . . . attention to the task in hand will automatically tend to shut out unpleasant and unhealthy introspection.

The development of recreational facilities as a further means for conserving individual and collective mental health is strongly advocated in the report which describes instances of effective work now being done along these lines by scores of communities alive to

the importance of leisure time activities as a morale measure.

The report also points to the mental health value of many of the activities now carried on by recreational, educational, religious, character-building and other social agencies faced with problems of human maladjustment.

The search for resources to bolster up morale and safeguard mental health does not necessarily nor always lead to the mental hygiene clinic or to the consulting room of the psychiatrist, indispensable as these facilities are in many instances. Today this search is likely to lead to the utilization of other resources which, until very recently, have seldom been thought of as having anything to do with mental hygiene.

Mental hygiene in its attempt to develop and preserve mental health becomes the responsibility of the whole community. It is something that cannot be isolated and apart. It is not special, separate, or unrelated to the rest of the community's daily life. It impinges on every one of our public undertakings. Its recognition moves all of our problems of unemployment back to the neighborhood of their source.—

CITIZENS' COUNCILS

THERE is a national movement to eliminate waste and secure the greatest possible public benefit from expenditure of public funds in each community. This movement has developed from informal conferences, in New York, Chicago, and Washington, of representatives of nearly fifty national organizations — educational, cultural, social, civic, governmental. It was clear that the end sought could not be achieved by any over-all national action, but only by appropriate coöperation of citizen groups in each community and state. It has therefore been agreed that the national organizations should encourage their members to participate in the organization of local Citizens' Councils. In many states it will be desirable also to have State Councils.

"The National Municipal League

has agreed to act as the national headquarters. Funds are being solicited from the Foundations for the necessary expense of this office.

"A Citizens' Council would enable some of the most intelligent, socially-minded persons of the community to learn what are the essential facts about needs, costs, wastes, and possible economies in all the public and semi-public services. Through the organizations which the members represent these facts should reach large numbers of the population. And when there are recommendations to be made to the public authorities, whether for elimination of waste or improvement of a service, the Citizens' Council, in coöperation with the constituent citizen groups, should be able to speak with a voice that can be heard above the claims of any special interest."

More specific information about the development of this movement, and more definite suggestions for the organization and work of Citizens' Councils, can be obtained by communicating with Carl H. Milam, Chairman for the Joint Committee of Representatives of National Organizations, at the American Library Association, 520 North Michigan Avenue, Chicago, Ill.

MOTHER'S DAY

UNDER the leadership of a carefully chosen medical board, the Maternity Center Association of New York is planning its third annual Educational Campaign for Mother's Day, May 14.

Medical Societies, Boards of Health, Women's Clubs and civic organizations joined last year in the campaign to teach the public the vital importance of adequate maternity care. This year the same general plan will be pursued, with meetings held by organizations interested in the subject throughout the country during the week preceding Mother's Day.

Material for use in connection with a local Mother's Day observance is available free on application to the Maternity Center Association, 1 East 57th Street, New York, N. Y.

EDISON AND INDUSTRIAL HYGIENE

TO Dr. Leverett D. Bristol, Health Director of the American Telephone and Telegraph Company, we are indebted for the following interesting quotation attributed to Thomas Edison, dean of American inventors:

Coming generations of inventors will have to do their pioneering in the field of health. Electric light, telephone, radio, talking picture, automobile, air-plane—these things we have. What we have not is control over our own lives and bodies comparable to our control over material things. . . . Sickness is pretty hard on the workman. . . . There is too much sickness. . . . Something will have to be done about it.—*Baltimore Health News*, Jan., 1933.

SOUTHERN CALIFORNIA ASSOCIATION ELECTS OFFICERS

AT the Sixth Annual Meeting of the Southern California Public Health Association, held in Los Angeles on February 24, the following officers were elected for the year 1933:

President, Dr. W. B. Wells, Riverside; *President-Elect*, Dr. C. W. Decker, Los Angeles; *First Vice-President*, Dr. C. M. Sellery, Los Angeles; *Second Vice-President*, W. S. Mangold, Los Angeles; *Secretary-Treasurer*, Thomas P. B. Jones, Riverside; *Representative on Governing Council of A.P.H.A.*, W. T. Knowlton, Los Angeles.

THE ECONOMIC ASPECTS OF MEDICAL CARE

BECAUSE of a demand for information and literature concerning the subject, the economic aspects of medical care, a list of reading references has been prepared by the Julius Rosenwald Fund, one of the agencies which contributed to the Committee on the Costs

of Medical Care. These are designed to be of service. Inquiries concerning the literature or other matters connected with the subject may be addressed to the Julius Rosenwald Fund, 4901 Ellis Avenue, Chicago.

Application of the Principles of Water Purification to the Control of Swimming Pools*

A. H. FLETCHER AND A. E. CLARK

*Sanitary Engineer, Department of Health, Memphis, Tenn.; and
Associate Engineer, State Department of Health,
Nashville, Tenn.*

UNTIL quite recently the regulation of swimming pools generally received very little attention from health departments, either state or municipal. Many pools, where insufficient funds handicapped them, were built without any designing, and were constructed as a concrete tank to be operated on the "fill and draw" principle. A small amount of fresh water was added daily, and occasionally the pool was emptied, scrubbed and refilled.

Recently a number of cities have taken an active interest in the proper operation of their swimming pools. There has been a more or less scientific development and a more exacting control of the operation of the pools in these cities. The possibility of transmission of disease in swimming pools did not seem to arouse much attention until the early part of the 20th century. In 1915,¹ Manheimer cited 19 authori-

ties who reported venereal, ocular, aural, or intestinal diseases in pools. Hinman, in 1929, classified the diseases which could be contracted in the swimming pool. The Joint Committee on Bathing Places, in 1929, reported on foot diseases.

Detroit² carried on some work on skin diseases, beginning in the fall of 1929 when a dermatologist was engaged by the Health Department to do special work along this line.

Among the most prevalent infections which would possibly result from swimming are the common cold and sinus and middle ear infections. There are available very few data giving definite information concerning the part played by a swimming pool in the transmission of communicable diseases. The consensus of opinion of authorities seems to be that there is a potential danger of person to person transmission of pathogenic bacteria added to the pool by swimmers, and that this danger may be greatly minimized or eliminated by an efficient disinfecting agent

* Read before the Public Health Engineering Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 27, 1932.

such as chlorine. It is also believed that perhaps the greatest danger is of auto-infection, meaning the transfer of organisms harbored by the individual to more susceptible parts of the mucous membrane or the irritation or removal of protection from the membranes, resulting in an attack by organisms already there. From the standpoint of actual health protection afforded, and also esthetic considerations, it is now generally granted that facilities for effective sanitary measures and close supervision of the application of these measures is necessary and justifiable.

DEPARTMENT OF HEALTH PROBLEMS

The problems encountered by a city health department in developing a municipal swimming pool program usually indicate the following procedures:

1. A study of the existing pools and collection of data on each pool as to construction, equipment, and operation
2. A study of swimming pool control programs in other cities and states by correspondence and actual visits and by accumulating copies of rules and regulations successfully used
3. The preparation of a swimming pool ordinance to control existing swimming pools and to provide for approval of design and construction of new swimming pools
4. The initiation of a program of systematic supervision including all pools
5. Securing coöperation of all swimming pool owners and operators in furnishing monthly reports and making recommended improvements
6. Development of a sound educational program by which the public will be informed and induced to select only the safest places for swimming

A state-wide problem in the control of swimming pools has been created by the stimulation of interest in bathing and swimming. This interest has been created through health education, extensive advertising, and automobiles making it easy to travel greater distances for recreational purposes.

The construction of a large number

of artificial pools in late years has been partially due to the increasing pollution of streams and other natural bathing places.

Education of the public has created an attitude demanding an acceptable water in pools. The owners expect regulations and look to the city and state health departments for advice and recommendations for proper operation. Those contemplating the construction of new pools want advice regarding all points which will affect the operation and production of a satisfactory water.

State departments of health are expected to and have a responsibility to give competent advice on the operation of swimming pools. In actual practice these departments are faced with a wide variety of problems. Equipment and other facilities range from nothing to the modern well equipped efficiently operated natatorium. Immediate results must be obtained in spite of inadequate equipment and makeshift operation, and at the same time recommendations of the department must be successful in order to obtain improvements as recommended. The study covered in this paper was made for the purpose of obtaining additional data and experience to be used as a basis for more authoritative technical service by health departments.

DEVELOPMENT OF THE CONTROL AND STUDY PROGRAM

No record or evidence of any effort on the part of the health department to control swimming pools can be found previous to 1929. Samples of water have been collected each year apparently for information without any effort to better conditions.

Early in the year 1930, it was decided to develop a swimming pool program in Memphis and part of the time of one inspector was assigned for the regular collection of samples for

bacteriological examinations and to instruct the owners and operators of swimming pools in the use of chlorine for swimming pool disinfection.

An attempt was made to assemble accurate information on quality of water and method of operation since 1922. The averages of bacterial counts on the total samples taken from all pools by the City Health Department are shown by years in Figure 1. A rapid improvement is noted after the year 1926. No comprehensive or reliable records of operation were found to be available. A monthly report form was prepared and put into immediate use, including all pertinent operating data and results of bacteriological examinations, the last being filled in at the City Health Department office.

A coöperative arrangement was approved, under which a sanitary engineer of the State Health Department was assigned to work with the Division of Sanitation of the Memphis City Health Department throughout practically all of the bathing season of 1931, in order to carry out a control and study program covering the various points mentioned. This program was carried out by the writers, assisted in routine work by a full-time sanitary inspector of the city.

A systematic survey of 14 of the principal pools in the city was made, a tabulation of the data obtained being given in Table I. A study of this indicated that on account of the wide variety of conditions with reference to construction, equipment, bathing load, and ability to make extensive improvements, some revision of the proposed ordinance would be necessary. The principal effect of these changes was to make allowance for light bathing loads, unusually good operation, and other favorable conditions, and under favorable conditions to extend the time limit within which complete equipment

would be required on existing pools. Strict requirements for new pools remained in the ordinance as finally passed in July, 1931. The control and study program was carried out under this ordinance, a copy of which may be obtained from the City Health Department of Memphis.

FIGURE 1
DEPARTMENT OF HEALTH, MEMPHIS, TENN.

Each pool was required to have an orthotolidine testing set, either a commercial set or an inexpensive one made up by the City Health Department. Daily records of operation available for examination by health officials were required. The routine duties of the inspector carrying out the control program included, a visit to each pool at least once a week, personally checking residual chlorine in the pool, and collecting samples for bacteriological examination. Two samples were regularly collected from each pool, one from the shallow and one from the deep end, the orthotolidine test being made at the same point and at the same time. The location of the sampling point, and time of weekly visits to various pools, were varied. Pool owners were notified by mail of the results of examinations and instruction by visit was given when laboratory reports were found unsatisfactory. Routine instructions were given to maintain the residual chlorine between 0.2 and 0.5 p.p.m. at all times a pool was in use.

EXPERIMENTAL STUDIES—GENERAL

A survey of the swimming pools in Memphis showed 14 pools in 1931 with approximately 250,000 swimmers and an additional 6 suburban pools patron-

ized by Memphis people. The problem in Memphis was to control and raise the standard of these pools, all but 2 of which had been built previous to 1926 and one of them as early as 1909. They

presented a multiplicity of problems with only about one-half of them "recirculating" pools, several of these with distinctly poor distribution of inlets and inlet flow and with turn-over

periods varying from 46 hours to 10 hours. Four of the latest designed pools were equipped with ultra-violet ray machines, while 3 were equipped with chlorinators.

The bacteriological examination of samples soon showed that it was impossible to obtain counts below 200 per c.c. and absence of *B. coli* in 10 c.c. portions without the use of chlorine or chlorine compounds. The problem of securing better distribution of chlorine in the recirculating pools and of maintaining chlorine residuals in pools where it was necessary to add chlorine by hand made it necessary to study the various types of pools with regard to chlorine disinfection, distribution of inlets, use of anhydrous ammonia and ammonium sulphate to maintain residuals, control of algae, and other problems.

The major portion of the experimental work was devoted to a study of disinfection of pool waters from the standpoint of chlorine and chlorine compounds alone and in conjunction with ammonia and ammonium sulphate using machine and hand application. The primary object was the uniform production of a water which would meet the drinking water standards of the U. S. Public Health Service. Standards of bacterial quality are not uniform between various states, but since the average bather will swallow some water while in the pool the writers believe that it should meet the above standards. The study was conducted with this in mind, and to find whether it is practicable to apply such a rigid standard to pool waters.

The studies included the practicability of enforcing changes on existing pools which do not have equipment sufficient to meet the demands of present-day practice, such as filter capacity for an 8- or 12-hr. turn-over, scum gutters entirely around the pool, proper inlets, number and spacing, apparatus for the application of chlorine gas and anhydrous ammonia.

Further study was devoted to the sand beaches, the control of algae and slime on the floors of pools. There was some question whether sand beaches

using relatively clean sand would prove detrimental to the pool water, and whether under these circumstances it would be necessary to require the installation of additional showers to be used by each bather before returning to the pool. Slime on the floors of pools has caused considerable trouble and its elimination by the use of chlorine was studied.

Algae control did not receive as much consideration in this study as its importance would indicate since it is a major problem in most outdoor pools. Some data were obtained during this past summer at 2 new pools located in Nashville, Tenn.

Three pools were selected for study. The Municipal Fair Grounds Pool, 1,125,000 gal. capacity varying in depth from 3" to 10' was selected on account of its equipment which consisted of a complete recirculating system capable of turning the pool over in approximately 48 hrs., two Wallace & Tiernan vacuum type chlorinators, and an ammoniator. The pool is arranged as shown in Figure 2, equipped with a scum gutter extending entirely around it, inlets spaced entirely around the pool, a sand beach extending approximately one-half the distance around it, and compulsory showers. Good superintendence, supervision, and operation are provided, and spectators are excluded from the pool walkway and beaches by a metal fence.

The East End Pool, rectangular, holding approximately 400,000 gal., has recirculating equipment sufficient to turn the water over in 27 hrs. at the rate of 3 gal. per sq. ft. of filter sand area and a chlorinator of Wallace & Tiernan manufacture type M.S.A. A scum gutter is provided only at the deep end with sand beaches at each end. The inlets, 4 in number, are at the shallow end (Figure 3). Showers are not compulsory. Water varies in depth from 2' to 11'. It was necessary dur-

ing the period of this study to apply chlorinated lime solution and late in the season ammonium sulphate by hand. Spectators are not allowed on the pool walkway or beaches.

Malone Pool is municipally owned, holding approximately 400,000 gal. and varying in depth from 3' 9" to 10', nearly square, and with a scum gutter at one end. Located 22' below normal ground level it is a problem to keep surface wash out during heavy rains. A sand beach is located at one end. No equipment is available at this pool and all disinfection was accomplished by hand. Access can be had to the pool on all sides, no admission is charged nor are showers compulsory. Figure 4 shows the layout of this pool.

Samples for bacteriological examina-

tion were collected daily, except Sunday, from each pool. Four samples were collected from the Fair Grounds pool and 2 each from the others. Total count on agar 37°—24 hrs. was determined on each sample and tests for *B. coli* were made of 10 c.c. portions in standard lactose broth. *B. coli* results were partially confirmed. Three 10 c.c. portions were run on the Fair Grounds and East End Pools and one 10 c.c. on the Malone Pool samples. Practically all samples were collected during bathing periods, and usually during the heaviest bathing load. Samples were taken to the laboratory immediately and planted at once.

Tests for residual chlorine were usually made twice daily, morning and afternoon at the time and place the

FIG. 2

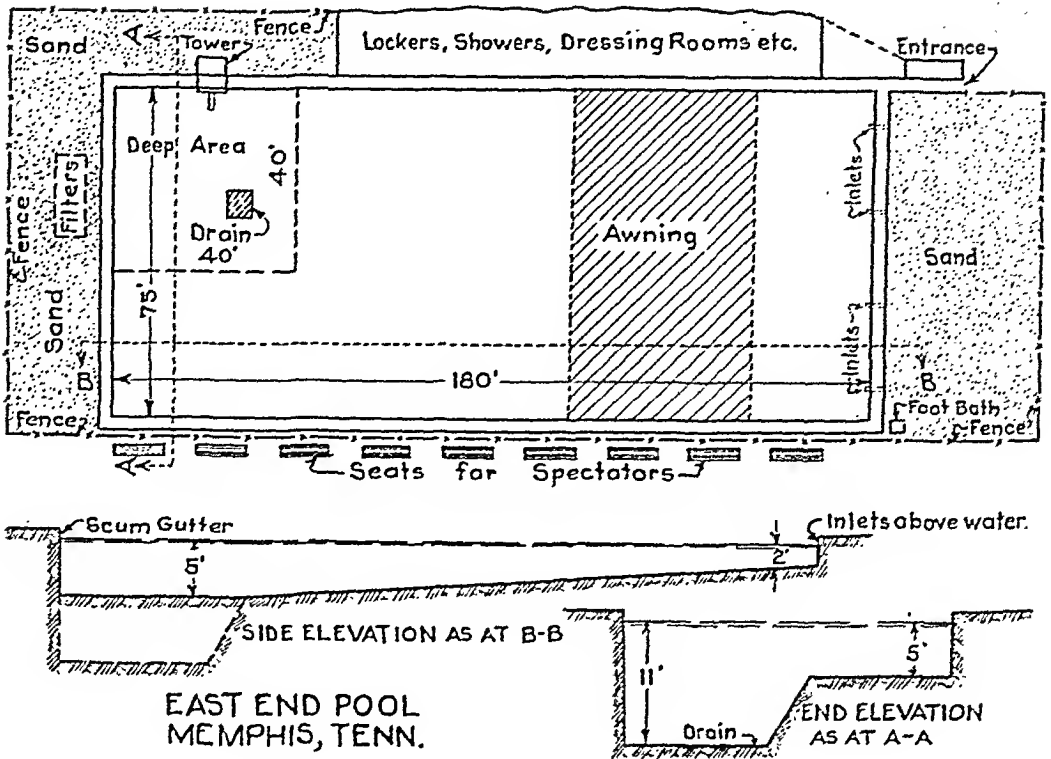

FIG. 3

samples were collected. Hydrogen-ion tests were made sufficiently often to show any marked variations. Operating data, such as hours the filters were operated, chlorine and ammonia used, water added, bathing load, air and water temperature, were kept as accurately as possible. A special series of examinations was run to determine the latent disinfecting value of the pool water using chlorine and ammonia.

Close supervision was given to the operation of the pools and at each suggestions made by the writers were complied with. Draining of the pools has been at frequent intervals, never more than 1 week elapsing between. A study was made to observe the effect of lengthening the intervals between draining.

Some data were collected on the cost at the Fair Grounds Pool, particularly of chlorine, ammonia, and water.

A short study was made of a salt water pool with particular reference to

infections of the respiratory and aural tracts.

Particular attention was given to complaints from the bathers due to smarting of the eyes, especially when high residuals were carried, using chlorine and ammonia.

DETAILS OF EXPERIMENTAL STUDIES *Pool No. 1—Fair Grounds Pool—* This is the first season during which

any concerted effort has been made to study the operation of this pool, either from the standpoint of economy or better and more efficient operation. Before going into details regarding the study, the results of bacteriological examinations for previous years are given in Table II.

In previous years it has not only been difficult to distribute the chlorine equally throughout the pool, but excessive doses have been required to obtain even a trace in the middle. Following are the quantities of chlorine and ammonia used from 1928 to 1931, inclusive, with the cost.

It has been the practice to drain and clean the pool each week. This was done on Sunday nights, the pool remaining drained part of Monday, and refilled for use Tuesday morning. The costs of water for the years 1928-1931 are given in Table IV.

TABLE IV

| Year | Total Cost of Water | Days Operated | Average Cost Per Day |
|------|---------------------|---------------|----------------------|
| 1928 | \$2,648.64 | 93 | \$28.50 |
| 1929 | 3,469.15 | 88 | 39.50 |
| 1930 | 2,928.77 | 86 | 34.00 |
| 1931 | 1,784.03 | 75 | 26.50 |

The attendance during the years 1928-1931 has not shown any marked variations (see Table V).

TABLE V

| Year | Total Attendance | Average Daily |
|------|------------------|---------------|
| 1928 | 82,040 | 880 |
| 1929 | 79,309 | 900 |
| 1930 | 82,218 | 960 |
| 1931 | 67,762 | 905 |

The pool was opened on June 6, at which time only chlorine was being used. Both chlorinators were operated at capacity, applying approximately 40 lb. of chlorine per 24 hrs. Residual chlorine tests taken at 10 different points in the pool showed erratic results, varying from a trace in the deep part to more than 1.0 p.p.m. in the shallow portions. When the ammoniator was started, one chlorinator was shut down and the other left on, set at 30 lb. per day. The ammoniator was set at 5 lb. per day. After operating 24 hrs. an increase was noted in the residual chlorine content, and particularly in the middle of the pool a very noticeable increase was found. On the second day the residual chlorine tests were uniform all over the pool at whatever point it was tested. On the third

day residuals greater than 1.0 p.p.m. were found at all points. The Enslow Comparator was used for making all residual tests, and color was developed at the end of 4 minutes.

Throughout the use of ammonia-chlorine a definite cumulative effect was observed, most pronounced when the water was fresh and contributions of organic matter by heavy bathing loads at a minimum. For example, it was sometimes necessary to shut off both machines for periods varying from 4 to 24 hours in order to reduce chlorine residuals and to reduce the dosage when the chlorinators were started again. In order to maintain effective residuals it was necessary to increase chlorine dosages during the latter part of the 2-week period between cleaning and refilling the pool (Figure 5). It was also

observed that an increase of the use of copper sulphate up to approximately 3.5 to 4 p.p.m., applied every third day, tended to reduce the chlorine demand, presumably by more effective control of algae, and to restore the cumulative effect of the ammonia-chlorine application.

Considerable attention was given to the bathers, particularly complaints of smarting of the eyes. There have been very few complaints made during this season. The pool manager has stated once or twice when the residuals were 1.0 p.p.m. he noted a smarting of his eyes.

During the period June 6 to August 8, 178 samples were collected from this pool for bacteriological examination. Figure 2 shows the location of the sampling points, which are numbered

FIGURE 5

9, 10, 11, and 12. Sampling points 11 and 12 are in water approximately 3' deep, while 9 and 10 are in the deepest part of the pool.

The results of the examinations during this period are shown graphically in Figure 6. The average number of bacteria per c.c. is 117. Eleven samples in 3 days showed high counts which totaled 16,900. However, on these days samples were collected by a person not accustomed to sampling. This must have been the reason for erratic results, since the residual chlorine tests on these 3 days indicated sufficient to produce low counts. Therefore, these results have been discarded and the average for 167 samples is 7 bacteria per c.c. The residual tests have varied from a trace to over 1.0 p.p.m. The results obtained indicate that with residuals between 0.2 and 0.5 p.p.m. uniformly low counts can be expected. With residuals less than 0.2 p.p.m. results may be erratic as indicated by an example. On different days each with water 12 days old and an average residual of 0.12 p.p.m. the average bacterial counts on 4 samples were 206 and 0.5 respectively.

The results of *B. coli* determination have been satisfactory, in that of 534 portions tested, only 4, or 0.75 per cent, have shown evidence of *B. coli* and after June 15 no portions were found positive (see Figure 6). Of the 4

positive portions mentioned above, 3 were from a single sample, having a zero bacterial count, an erratic result to which the writers attach little significance.

The total amount of chlorine used during 75 days of operation was 1,450 lb. Six days ammonia was not used, and the chlorine consumption during this time was 250 lb., an average of 41.7 lb. per day, or 4 p.p.m., based on total pool capacity. During 69 days a total of 253 lb. of ammonia was used, together with 1,200 lb. of chlorine. This shows while using ammonia-chlorine a daily average of 17.4 lb., or 1.7 p.p.m. of chlorine and 3.7 lb., or 0.35 p.p.m. of ammonia. The average ratio of chlorine to ammonia was 4.2 to 1. The ratios were varied over a wide range, the maximum being 12 to 1 and the minimum 1.25 to 1.

FIGURE 6

The cost of chlorine this season has been \$.09 per lb., and the ammonia averaged \$.1925 per lb. The average daily cost of using the chlorine ammonia process during 69 days was, chlorine \$1.56 and ammonia \$.71. The

average daily cost of using chlorine during the 6-day period was \$3.75. These figures show that there was an actual saving of \$1.48 per day using the chlorine ammonia process, assuming that results were comparable. Daily averages, showing quantities and cost of chlorine, for entire season of 1928 to 1931 inclusive have been given already in Table III.

The total number of bathers from June 6 to August 1, was 55,365, an average per day of 1,130, the maximum number on any one day being 3,193 and the minimum 21.

The water temperatures during the period June 6 to August 1, varied from 80° to 86° F. Although no correlation between water temperatures and sanitary quality was observed high temperatures will cause complaints from bathers and in southern states this may be the factor controlling frequency of draining outdoor pools.

The recirculating system operated 24 hrs. per day. Water was added each day to replace that lost as well as to flush the surface. The amount recirculated varied from 400,000 to 640,000 gal. per 24 hrs., with an average of 565,000 gal. Water added each day averaged 72,000 gal. The practice of draining and cleaning the pool each week was discontinued and the interval lengthened to 2 weeks. At all times during the season it has been easily possible to see the bottom in the deepest part of the pool.

The interval between draining could have been lengthened except for the slime which formed on the floor of the pool. The practice has been to drag 5 lb. of copper sulphate around the pool every other night. An increase of copper sulphate dosage to 7 lb. every 2 days was beneficial and a dosage of 50 lb., or 3.5 to 4 p.p.m. every third day was effective in killing algae after which the vacuum cleaner would pick up the slime. High chlorine residuals

apparently would not prevent slime formation.

Determinations of pH were made at frequent intervals over a sufficient length of time to show that it is relatively constant and shows little variation. The minimum found was 7.4 and the maximum 7.6.

Pool No. 2—Malone Pool—Drainage facilities at this pool are very poor and a noticeable amount of mud accumulates on the sand beaches following every heavy rain. Water accumulates in depressions in the sand and bathers carry a certain amount of mud into the pool. This accounts to a large extent for the very noticeable turbidity 2 or 3 days after the pool has been cleaned and filled. It makes disinfection more difficult and less reliable (Figure 4).

Disinfection, in the absence of mechanical equipment, must be accomplished by hand application. Chlorinated lime, used at the rate of 15 lb. per day failed to show any positive residual tests. Assuming that the chlorinated lime contained 25 per cent available chlorine, this would be equal to 3.73 lb. of chlorine, or 1.13 p.p.m.

The writers gave this phase of the treatment considerable thought and it was finally decided that because of a high chlorine content, greater stability and ease in dissolving H.T.H. would be the most suitable chlorine compound. From previous experience it was felt that ammonia would be necessary to obtain residuals and, therefore, a technical grade of ammonium-sulphate having an NH_3 content of approximately 25 per cent was used in conjunction with H.T.H., providing a ratio of 5 to 1 chlorine to ammonia.

Ammonium sulphate was first used on June 23 and June 24. This preliminary test indicated that residual chlorine of 0.2 p.p.m. or better could be maintained throughout the day. After waiting for an additional supply

of ammonium sulphate the ammonia-chlorine treatment was again started on June 30 and continued with minor interruptions throughout the season.

A study of the results indicate that chlorine residuals can be maintained over a greater period of time by using ammonia, and ultimately there will be an overlapping from day to day with a cumulative effect previously mentioned. For example, on the morning of July 16, 8 lb. of H.T.H. and 4 lb. of sulphate were added. On the morning of July 17 the residual was 0.5 p.p.m. at all points and without further chlorine application on the morning of July 18 the residual was 0.1 p.p.m. at all points. The bathing load at this time was light. Typical results during a heavy bathing load would show 0.7 p.p.m. after treatment, 0.5 p.p.m. in the middle of the afternoon, and 0.2 p.p.m. on the following morning.

During the period from June 18 to August 1, 60 samples were collected. The majority of samples were collected between 1:00 and 2:00 o'clock in the afternoon, but quite a number of them were collected in the morning—usually before the chlorine or chlorine and sulphate had been added in order to determine the condition of the water several hours after disinfection and to reflect the addition of organic matter by the bathing load of the previous day.

The average number of bacteria per c.c. for the 60 samples was 664. Thirty-two samples were collected when the residual test showed 0.2 p.p.m. or above, with a maximum count of 100 and a minimum of 0. The remaining 28 samples were collected when residuals were less than 0.2 p.p.m. and, as already explained, many in the early morning before treatment.

Of 60—10 c.c. portions tested 18, or 30 per cent, showed evidence of *B. coli*. Of these 10 positive tests were on samples collected before any disinfection had been added that day.

A concise summary of quantities of disinfectant used during the entire season is not possible because chlorinated lime and H.T.H., both with and without ammonium sulphate, were used interchangeably, depending upon the supply on hand. In general, it may be stated that chlorinated lime, applying a dosage of 0.76 p.p.m., used without ammonia, failed to show any test for residual chlorine. The use of H.T.H., providing 2.2 p.p.m., available chlorine, would show residuals above a trace throughout the pool for a varying period of time, depending on the bathing load and the amount of organic matter in the water. The use together of H.T.H. and ammonium sulphate, providing average dosages of 1.45 p.p.m. of chlorine and 0.26 p.p.m. of ammonia, was sufficient to show residuals of 0.2 p.p.m. or better throughout the day. This is a ratio of 5.6 to 1.0, chlorine to ammonia.

Pool No. 3—East End Pool—Tests made during the 1930 season showed definitely that with the dosage of chlorine applied to this pool by the chlorinator, residuals were found only about 20' from the inlets. In order to supplement the chlorine dosage from the chlorinator, a practice was made of adding a solution of chlorinated lime directly to the pool water.

The procedure for disinfection is somewhat out of the ordinary in that chlorination by means of a chlorinator was used, as well as hand application of chlorinated lime solution and ammonium sulphate. During the period June 16 to July 2 a solution of guaranteed 33 per cent chlorinated lime was used. According to the best figures obtainable, the accuracy of which the writers have some doubt, the average used was 16.1 lb. per day, a dosage of 5.3 lb., or 1.61 p.p.m. of chlorine. To this must be added the average amount of chlorine applied through the chlorinator, assumed to be 2.5 lb. per day,

averaging a total dosage of 7.8 lb., or 2.37 p.p.m. From June 16 to July 13 there was only 1 day on which the residuals were greater than 0.2 p.p.m., and the majority of the time they were either zero or just a trace. On July 13 the use of ammonium sulphate was started and it was used with either chlorinated lime or H.T.H. and also liquid chlorine during the remainder of the study. It was then possible to get residual tests above 0.2 p.p.m. fairly regularly, although there were times when lower residuals were found.

On August 8 the chlorinator began running 24 hrs. and after that time little difficulty was experienced in maintaining a residual between 0.2 and 0.5 p.p.m. in all parts of the pool. On August 11 the liquid chlorine dosage was increased to 8.8 lb. per 24 hrs. but on account of poor distribution this was found to cause odor near the inlets, and therefore, it was decreased to a dosage of approximately 5 lb.

It was found that the medium dosage of liquid chlorine in conjunction with chlorinated lime and ammonium sulphate solutions was most satisfactory in maintaining adequate residuals.

From June 16 to August 10, 93 samples were collected for bacteriological examination. The average of all bacterial counts was 558 per c.c.; 59 showed less than 200; and a majority of these less than 10. Checking total counts against chlorine residuals at sampling point, shows that in general with residuals of 0 or only a trace the count usually rises above 1,000 per c.c. There are relatively few samples showing greater than 10 bacteria per c.c. if the chlorine residuals were between 0.2 and 0.5 p.p.m.

A total of 279, 10 c.c. portions were tested for *B. coli*. A positive test was obtained on 15 or 5.4 per cent of the total. These *B. coli* results were more satisfactory than the total bacterial counts. During the period June 16 to

August 11 the number of bathers was 34,349, or a daily average of 613, with a maximum of 2,263 on June 28 and a minimum of 5 on July 23. The water temperatures have varied between 76° and 86° F., and again there did not seem to be any correlation between water temperature and sanitary quality.

Relatively little trouble from algae was experienced and relatively little slime formed on the bottom. Water has been left in this pool 11 days and the small amount of slime that did occur was confined to the deep portion.

Accurate figures not being available, it has been estimated that approximately 370,000 gal. of water per day were recirculated, but no estimate has been made of the daily quantity of make-up water added. The practice had been to drain, clean and refill this pool twice each week, but since starting 24-hr. operation of the recirculating system, it was seldom drained in less than a week.

Salt Water Pool at Monroe, La.—The pool at Monroe has a capacity of 1,500,000 gal. and an average depth of 3.5'. Walls are constructed of concrete with a sand floor. No scum gutters are provided. Disinfection is accomplished by adding liquid chlorine to the suction line of a 900 g.p.m. circulating pump, taking the water from one end of the pool and putting it back at the opposite. The salt water is obtained from a flowing well discharging into the pool approximately 400 g.p.m. A chemical analysis at the time these tests were made showed 1,250 p.p.m. of chlorides. The bacteriological results of 4 samples collected from the pool showed relatively low counts, but examination of previous records indicated that about 25 per cent of all 10 c.c. tubes showed gas formation, *B. coli* results not being confirmed.

Three eye, ear, nose, and throat specialists were visited and requested to state their opinions on 4 questions as

to the relative number of infections believed to have been contracted from bathing in fresh or in salt water; the cause of the infection whether from the water or mechanical injury; the advantages if any of swimming in salt water; on the comparative number of patients treated this season as against previous seasons.

As would be expected, the answers to these questions varied. Two believed that there is no difference between salt and fresh water either in cases treated or as to the advantages for bathing. One thought that salt water was beneficial from both standpoints. All believed that there was greater danger of infection due to mechanical injury rather than actual transmission through the water. No definite comparison of number of patients treated this season as against previous seasons was obtained.

Municipal Pools at Nashville, Tenn.
—Two municipal pools constructed during 1932 by the City of Nashville furnished an excellent opportunity to try out some ideas based on the Memphis study, and collect further data on operation. Experience in the design and first year's operation at these pools have confirmed the writers' opinion that exact hydraulic design of the system for distribution of water and chlorine to all areas is essential to success of operation.

The 2 pools are both of approximately the same capacity, with equipment and construction to comply as far as possible with present-day practice. The capacity of each is approximately 330,000 gal. An ammoniator is installed at each pool. Inlets are spaced around all sides and the piping as well as the inlet plates designed for equal distribution of the incoming water. Recirculating equipment is designed for an 8 hr. turn-over. With this design it is possible to note an increase of chlorine residual in the center of the

pool within about 30 min. after the chlorine dosage has been increased, and uniform distribution of chlorine is obtained.

Arrangements of dressing rooms, showers, toilets, etc., are satisfactory. Unfortunately both pools are located near trees, which have given considerable trouble, leaves falling into the pools, causing an increase in the chlorine demand, and interfering with the operation of vacuum cleaners.

Wallace & Tiernan chlorinators and ammoniators are used, the chlorinators having a maximum capacity of 10 lb. per day. During normal conditions this apparatus in conjunction with ammonia gave residuals varying from 0.2 to 0.7 p.p.m. Following a storm, during which a considerable amount of leaves and dust was blown into the pools, residuals dropped practically to 0 and following this it was impossible to obtain residuals greater than 0.15, operating the chlorinators to capacity, until after the pools were drained and cleaned. It is advisable to have apparatus of adequate capacity to take care of abnormal as well as normal conditions. Good bacteriological results have been obtained.

Uniform doses of copper sulphate have been added to each of the pools, averaging from 10 to 12 lb. every third day, corresponding to a dosage of 3.6 to 4.2 p.p.m. It has been necessary to shorten the interval between dosing on a few occasions due to growth of algae. This is noticed first on the walls, particularly back of the ladders. At these times the chlorine demand is increased and higher doses of chlorine up to the capacity of the chlorinator usually fail to raise residuals above 0.2 p.p.m. The residual immediately increases following a copper sulphate treatment.

Vacuum cleaners capable of removing leaves are necessary at these pools if a clean bottom and proper residuals are

to be maintained. Except for excessive temperatures and collection of sediment on the bottom it would be possible to operate these pools throughout the season without draining.

GENERAL OBSERVATIONS

Observations of the effect of sand beaches during this study have failed to show any deleterious effect on the water in any way, provided the sand is clean. There is an apparent beneficial effect since in those portions of the pool bordering the sand beach there was less slime on the bottom, due probably to the scouring action of sand carried into the pool by bathers. At Malone Pool, where the sand becomes dirty by flooding during heavy rains, additional turbidity and possibly an increase in chlorine demand resulted.

It was desired to know what, if any, latent disinfecting properties the pool water had, using the chlorine ammonia process. Samples from the Fair Grounds Pool were collected in sterile bottles and taken directly to the laboratory. The residual chlorine test was made at the time and point at which the sample was collected. Plates were poured and tubes sowed for *B. coli* immediately, and following this the sample was inoculated with a known number of *B. coli* in 10 c.c., 1.0 c.c., and 0.1 c.c. Samples were tested each minute for a period of 10 min. and then every 5 min. up to 30 min. (See Table VI.)

As a guide to the use of the ammonia chlorine process during the study and to obtain a comparison of maintenance of residuals by this process as against the use of chlorine alone two determinations of the rate of reduction of residual chlorine in the Malone Pool were made on different days. Orthotolidin determinations were made frequently enough to obtain curves showing the reduction of residual chlorine. (Figure 7.)

SUMMARY AND CONCLUSIONS BASED ON EXPERIMENTAL STUDIES

1. The present studies have included close supervision of, and experimental work on, 3 outdoor swimming pools in Memphis, supplemented by observation of several other pools.

2. The maintenance of satisfactory residuals of chlorine, using chlorine or chlorine compounds alone, has not been found practicable in the pools studied. In recirculation pools, perhaps on account of the long turnover period, there was too great divergence in chlorine residuals between inlets and distant points. In pools requiring hand application of chlorine compounds residuals disappeared rapidly and additional applications during a single bathing period is not satisfactory.

3. The maintenance of satisfactory residuals of chlorine, using chlorine and ammonia, in the 3 Memphis pools studied was found to be practicable. Where recirculation equipment and location of inlets for uniform distribution is provided residuals above 0.2 p.p.m. can be maintained easily. Where recirculation equipment is inadequate or distribution poor residuals throughout the day can be maintained by supplementing machine application with hand application once before the bathing period. Where recirculation is not provided residuals can be maintained throughout the day by a single application of ammonia and chlorine before the bathing period.

4. Hand application of chlorine and ammonia compounds is not as satisfactory as continuous application of chlorine and ammonia by machine. If hand application is the only method available a high test chlorinated lime and a technical grade of ammonium sulphate were found to be satisfactory. In such cases it is necessary to dose for high residuals at the time of application in order that adequate residuals will remain throughout the bathing period.

5. Experiments to determine relative rates of reduction in chlorine residuals, using chlorine alone and chlorine with ammonia, were made and the results show a much more rapid reduction when chlorine is used alone.

6. The rate of reduction of chlorine residuals is increased by heavy bathing loads, growths of algae, addition of dust or leaves, and any other condition increasing the organic content of the water. The effect of such conditions in causing disappearance of chlorine residuals is very pronounced with chlorine alone and noticeable when chlorine and ammonia are used. Variations in temperature

of the pool water did not have any apparent effect upon the distribution or maintenance of chlorine residuals.

7. Flexibility of design in order to obtain additional reserve capacity in chlorination equipment and immediate distribution through proper design of piping system and inlets to all parts of the pool is emphasized as the most satisfactory method of counteracting unusually high chlorine demands resulting from any cause. A short turn-over period and uniform distribution are also important from the standpoint of appearance of the water, affecting rapidly with which turbidity can be removed from the water itself and also accumulation of material on the bottom in the shallow portions.

8. Bacteriological examinations for total bacteria and *B. coli* have covered ranges of chlorine residuals from 0 to 1.0 p.p.m. In general these results show that between residuals of 0.2 and 0.5 p.p.m. low bacterial counts can be expected, the use of chlorine alone and the chlorine-ammonia combination giving comparable results. Less reliable disinfection, shown by erratic bacterial results, was obtained when chlorine was used alone, and when hand application of chlorine with ammonia was employed. No explanation is offered but at the pool operating equipment 24 hrs. a day no high counts were noted until residuals had dropped to 0.1 p.p.m., while in the case of 2 pools using hand application a number of high counts were found between 0.1 and 0.3 p.p.m.

9. It is assumed from a study of literature and previous experience that the disinfecting action of chlorine alone is more rapid than is that of chlorine-ammonia. Experiments to determine the latent sterilizing value of water containing chloramines were made, the results showing that with residuals of 0.3 to 0.5 satisfactory disinfection is obtained in about 20 min.

10. Complaints of smarting of eyes and irritation of mucous membranes led to the conclusion that higher residuals of chlorine and ammonia can be carried without danger of complaint than with the use of chlorine alone. Hydrogen-ion concentrations were maintained between 7.4 and 7.6, and it is the opinion of the writers that with proper pH control, and the use of chlorine and ammonia no complaints should result from maintenance of residuals as high as 1.0 p.p.m.

11. Clean sand beaches are not detrimental to the quality of pool waters provided spectators are not allowed access to them. Trees, while providing shade, cause trouble due to leaves falling into the pool, affecting the appearance as well as increasing the chlorine

demand. Dust is detrimental in that turbidity is added to the water with contamination.

12. Scum gutters are a necessity if a pool is to be kept in satisfactory condition. There is a relatively large accumulation of floating material which collects and does not settle out.

13. The taking of a shower bath before entering the pool is considered essential and use of showers must be made compulsory, as at least 50 per cent of those using the pools will not take them voluntarily. Satisfactory use of showers can be obtained only by proper location, continuous operation, and personal supervision.

14. From the limited opportunity for observation at Monroe, La., the authors find no apparent public health value in the use of salt over fresh water. However, one of the authors who suffers from hay fever every year experienced a decided relief after swimming in the municipal salt water pool at Monroe. The cost of using saline water in a pool is considered impracticable if salt has to be purchased, but the use of salty well water is practicable if sufficient quantity is available.

APPLICATION TO CONTROL OF SWIMMING POOLS

City—The Memphis swimming pool ordinance allows a period of grace not to exceed 5 years to bring the existing pools up to the requirements. The first year or two is being used by the Health Department to study each pool under actual operating conditions. The ordinance also provides that each pool shall secure each year from the Health Department a permit to operate.

Following each swimming pool

FIGURE 7

season, it is planned to arrange for a conference with the owner or operator of each pool and discuss needed improvements for that pool. Following this conference the department will address a letter outlining the required improvements which will be expected before issuance of a permit to operate the following year. These studies will enable the department to insist on practical and intelligent improvements.

As the results of these studies it appears possible to maintain water in a swimming pool which will meet the bacteriological standards for good drinking water. In order to encourage consistently good samples the Memphis City Health Department has adopted a grading schedule similar to that used in Detroit, Cleveland, and Cincinnati, announcing 4 times during the year the rating of all pools, based on the quality of the water as shown by bacteriological tests. The concern shown by each pool following the first grading announcement which did not reach a 900 to 1,000 rating, classed as "A," demonstrated that in future ratings, practically every pool will probably be in class "A" rating. Ratings have been announced 3 times to date. Each rating was based on the percentage of good portions tested multiplied by 10, a good portion being one with a total bacteria count below 200 or a negative partially confirmed test for *B. coli* in 10 c.c.

It is believed that these studies will be of value in cooperating with architects and engineers in the design of new pools, or in making major changes and in the approval of plans for construction submitted to the City Health Department under the provisions of the ordinance.

State—The study and experimental work at Memphis has furnished a guide which is most valuable in the formulation and execution of a state-wide swimming pool program.

A state program should include:

A sound educational program

Advice to local health authorities in regard to legislation and procedures

Advice directly or indirectly to pool operators

Collection of data through surveys or submitted reports as a basis for judgment regarding the extent to which the state health department can afford to go in a state-wide swimming pool program

Education of the public should proceed along the lines that will create an understanding of the necessity of swimming pool control and of patronizing those pools which produce a satisfactory water and maintain the pool and appurtenances in a manner which meets the requirements of state or local regulations in every respect.

The state department of health must be in a position to give expert advice to the local health authorities in drawing up swimming pool regulations, formulation of a swimming pool sanitation program and general advice in regard to operation.

The result of this study provided the department with additional data upon which advice to engineers and architects can be based, particularly regarding recirculating equipment required and inlet design. One problem of pool design which has given considerable trouble is the irregular distribution of chlorine, particularly when fed by machine with inadequate recirculating equipment and improper spacing and design of inlets. Clarity of pool waters has been a problem in a number of pools, especially those subject to heavy bathing loads and where insufficient filter capacity is provided.

Sound advice to the operators of pools is most important, because the quality of a pool water is directly dependent upon operation. Some supervision is necessary along with instructions for proper disinfection, orthotolidin tests, proper alum dosage, proper copper sulphate dosage, time interval between washing the filters, use

of the vacuum cleaner and application of soda ash if required. Operators of pools having inadequate or no equipment have a more difficult problem to maintain a good water and more attention must necessarily be given to operation of this type of pool.

The active participation of the state department of health in promoting swimming pool control programs should lead toward standardization throughout the state and make the individual programs of various cities comparable.

GENERAL SUMMARY

The historical outline of the growth of swimming pools dates from 312 B.C., while the early development in purification of swimming pools in the United States dates from 1906. The interest in disease transmission in pools seems to have aroused very little attention until 1915. In the development of a state and municipal swimming pool program, certain problems were encountered.

Beginning in 1930 a swimming pool program was initiated in Memphis. A survey of the situation was made and other cities were visited and their programs observed. A coöperative arrangement between the city and state

was made to study the problem jointly. A swimming pool ordinance was finally passed in July, 1931, and a program of systematic supervision of all pools was instituted.

Between the years 1909 and 1926, 19 pools were built in Memphis. Thus a multiplicity of designs and problems were presented and it was found necessary to make a special intensive study of 3 general types before intelligent progress could be made in a practical program. Experimental studies were made and certain conclusions were reached. In addition to the pools in Memphis, limited information was gathered on a salt water pool and observations made on 2 newly constructed pools in Tennessee. Following these studies it has been possible to indicate certain applications to municipal and state swimming pool control programs. This presentation and discussion are given hoping that they may be of some value in other places.

Injuries Produced by Contact with Electric Circuits

AN extensive article summarizes earlier studies, the various factors provoking electrical mishaps, the ascertained cause of death and the effects upon the nervous symptoms, the heart, the blood pressure, the skin, musculature, blood vessels, and other less important points of localization.

Under several of these headings, the authors report their own findings, principally upon rats, but also some autopsy findings on 2 men who were electrocuted. There are also brief

resumés of the subject of treatment and of permanent disability. The general impression should be corrected that low voltage circuits need no precaution. "A time has come when it is important to give wide publicity to the possible dangers. The sale of poorly insulated electrical devices for the home should be prohibited." A bibliography of recent articles follows.—Orthello R. Langworthy and William B. Kouwenhoven, *Am. J. Hyg.*, 16, 3:625-665 (Nov.), 1932. E. R. H.

Risk of Persons in Familial Contact with Pulmonary Tuberculosis*

W. H. FROST, M.D., F.A.P.H.A.

*Department of Epidemiology, School of Hygiene and Public Health,
The Johns Hopkins University, Baltimore, Md.*

DURING the past 2 years various workers in this department have collaborated in two epidemiological studies of tuberculosis; one concerned with the families of children registered in Dr. Edwards A. Park's clinic for tuberculous children at the Johns Hopkins Hospital; the other a series of studies carried on by a special unit of the State Department of Health of Tennessee in various localities in that state. The several studies have varied in scope and in certain details of method, but a purpose common to all of them has been to ascertain the mortality and specific morbidity in familial contacts of persons suffering from pulmonary tuberculosis, for comparison with the experience of suitable control populations.

The data so far accumulated are not sufficient to be of much significance as actual measures of even the gross average risks. They are sufficient, however, to afford material for preliminary investigation of the antecedent question whether records of the kind represented are at all suitable for the purpose in view. It is to this question that the present discussion is directed, the actual records of a small group of families being introduced only for purposes of illustration.

For the acute communicable diseases, such as diphtheria, scarlet fever, and measles, measurement of the morbidity risk of familial contacts is a simple procedure, because the excess risk is concentrated within the few weeks following invasion of the household. As was pointed out by Chapin years ago, all that is necessary is to ascertain, in each invaded household, the number of persons present, other than the one first attacked, with particulars as to sex, age, and many other variables which are to be considered; then to ascertain the number of cases of the same disease subsequently occurring in the various exposed groups within a stated period of, say, 4 to 6 weeks. This attack rate may then be compared with the average rate in the community at large for a like period of time. Collection of the data is simple because, for any family, the required period of observation is brief; and compilation is simple because the period to which the attack rate refers may be taken as the same for all families.

For tuberculosis the requirements are essentially the same, but are more difficult to meet, chiefly because the disease is of slow evolution, and we cannot assume that the risk with which we are concerned is concentrated within the year or even the decade following establishment of the known exposure. It may, perhaps, be manifested by excessive morbidity or mortality in any

* Read before the Epidemiology Section of the American Public Health Association, at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

subsequent period of life. Hence, observation of the exposed group must extend over a sufficient number of years to define the rates of morbidity and mortality prevailing in successive periods throughout the usual span of life. To keep a sufficiently large group of people under systematic, exact observation for such length of time is a difficult task which has, indeed, been undertaken in various places, but to the best of my knowledge has not been carried much beyond a decade. However, such simple facts as lie within the knowledge and memory of the average householder may be obtained by *retrospective* investigation, tracing familial histories backward into the past. The procedures followed in a preliminary attempt to apply data collected in this way and to check their reliability may be described best by referring to a concrete example.*

The available records which best serve the purpose of illustration are from a survey of the negro population of Kingsport, Tenn., made during 1930 and 1931 by a special unit of the Tennessee State Department of Health.†

The survey covered 132 families, constituting practically the entire negro population of the city.‡ For each family the investigation included a detailed familial history, extending as far back as practicable, and examination of every present member in a special clinic, where the routine procedure was: physical examination, roentgenogram of the chest, and tuberculin test. With very few exceptions, the full schedule

of examinations was carried out for all persons, regardless of whether or not there was any reason to suspect tuberculosis.

In addition to numerous other items which do not come into the present discussion, each family schedule gave the following:

1. Date of establishment of the household, which may be defined more exactly as the date when the present head of the household came into that position. This is an important item, as it marks the date from which at least one informant may be expected to have first-hand knowledge of occurrences within the household.

2. A list, by name, of all persons present in the household when the schedule was made out, giving, for each person: familial relationship, date of entrance into household, age at time of investigation, record of any present or past illness diagnosed as certain or probable tuberculosis, record of clinic examination, and a detailed account as to time and circumstances of any known household contact with antecedent cases of pulmonary tuberculosis.

3. A list, by name, of all former members of the household, giving, for each: age at which entered the household, record of known or suspected tuberculosis while in the household, record of household contact with antecedent cases of phthisis; age at which withdrawn from the household, status when withdrawn—whether living or dead—and, if dead, date of death, with ascribed cause.

These records were made with great care, each family being revisited as often as necessary to check and complete the information; and as the families were thoroughly coöperative, it is believed that the facts within their knowledge were stated with fair accuracy. From the histories obtained, it is probable that the deaths ascribed to pulmonary tuberculosis actually were due to that cause; but it is by no means certain that these were all the deaths attributable to tuberculosis, and as to non-fatal cases of this disease the histories, both negative and positive, obviously are subject to considerable error. Also, the *early* history of *former* members, who were born outside of the households in which they were recorded,

* The procedure, except in collection of data, would be essentially the same in analysis of records obtained by keeping a group under planned observation.

† It is expected that a detailed report of the studies in Kingsport will be made from the State Department of Health of Tennessee.

‡ The federal census of 1930 gives the negro population of Kingsport as 596. The persons living and present in the families surveyed numbered 556. Only 3 families are known to have been omitted (because of unwillingness to be examined), but it is probable that a few others may have been missed.

must often be unknown. However, in general, the facts are simple and, for the period since establishment of each household, presumably within the knowledge of the informant.

The whole group of 132 families furnished records of 794 present and former members, classified as follows:

| | |
|--|-----|
| (1) Living and present at time of survey | 556 |
| (2) Former members of same households, not present at time of survey | |
| (a) removed, living | 142 |
| (b) dead, (27 of tbc., 69 of other causes) | 96 |
| | 238 |
| Total: present and former members | 794 |

Before discussing mortality and morbidity from tuberculosis as related to history of known household contact with the disease, it is desirable, as a description of method and a check of the data, to compare the mortality from all causes in the entire group with the current mortality in the negro population of the state as a whole. The force of mortality in the population of the state is expressed in terms of the annual death rate, that is, the ratio of deaths to persons under observation for

a period of 1 year and, since this rate varies widely with age, it is necessary for significant comparisons that it be stated separately for each age group. We need, therefore, to reduce the mortality of the Kingsport families to these same terms, namely, age-specific annual death rates. To accomplish this, it is necessary to convert the observations on the family group to terms of life-experience, of which the unit is 1 person under observation for 1 year, or 1 person-year. The procedure to this end, which is an application of the familiar principles of life-table construction, is illustrated in Table I, which shows in detail the summation of life-experience within the age-limits 0-5 years.

As indicated in this table, 363 children, born in the families to which they are allocated, came under observation at the beginning of the first year of life. Of these, 18 died within their first year, and 15 others were less than 1 year old when the record was taken, so that a total of $18 + 15 = 33$ were withdrawn from observation before completing the year. Counting each person withdrawn before the end of the year as having been in the household $\frac{1}{2}$ year, we have as the aggregate

TABLE I

SUMMATION OF LIFE-EXPERIENCE AND MORTALITY BETWEEN THE AGE-LIMITS 0-5 YEARS IN 132 NEGRO FAMILIES

| Year of Age | Number present at beginning of year | Number added during year | Number withdrawn (living) during year | Number dying during year | Mean number present during year | Death rate per 1,000 during year |
|--------------|-------------------------------------|--------------------------|---------------------------------------|--------------------------|---------------------------------|----------------------------------|
| x to $x+1$ | l_x | n_x | w_x | d_x | L_x | m_x |
| 0-1 | 363 | 0 | 15 | 18 | 346.5 | 51.9 |
| 1-2 | 330 | 3 | 3 | 4 | 328.0 | 12.2 |
| 2-3 | 326 | 3 | 16 | 6 | 316.5 | 19.0 |
| 3-4 | 307 | 4 | 12 | 0 | 303.0 | |
| 4-5 | 299 | 5 | 14 | 3 | 293.0 | 10.2 |

The derivatives from the primary figures (l_x , n_x , w_x , d_x) are:

$$l_{x+1} = l_x + n_x - w_x - d_x.$$
$$L_x = l_x + \frac{1}{2} (n_x - w_x - d_x).$$
$$m_x = 1000 \cdot \frac{d_x}{L_x}$$

TABLE II

MORTALITY FROM ALL CAUSES, BY AGE, IN NEGRO FAMILIES OF KINGSFORT, FROM DATE OF ESTABLISHMENT OF EACH FAMILY TO DATE OF EXAMINATION, AND MORTALITY RATES IN NEGRO POPULATION OF STATE, 1920

| Age | Negro families of Kingsfort | | | Negro population of Tennessee. |
|---------|---------------------------------|--------------------|------------------------------|--------------------------------|
| | Person-years of life-experience | Deaths, all causes | Annual Death rates per 1,000 | Death rates per 1,000, 1920 * |
| Under 1 | 346.5 | 18 | 51.9 | 120.0 |
| 1-4 | 1,240.5 | 13 | 10.5 | 14.0 |
| 5-9 | 1,259.0 | 7 | 5.6 | 4.0 |
| 10-19 | 1,916.5 | 17 | 8.9 | 7.1 |
| 20-29 | 2,190.5 | 15 | 6.8 | 15.0 |
| 30-39 | 1,557.5 | 13 | 8.3 | 17.0 |
| 40-49 | 764.5 | 1 | 1.3 | 17.4 |
| 50-59 | 308.5 | 8 | 25.9 | 26.1 |
| 60+ | 88.0 | 4 | 45.5 | 67.0 |
| Total | 9671.5 | 96 | 9.9 | 18.0 |

* From U. S. Mortality Statistics, 1920.

of life experience between the age-limits 0-1 year, $363 - 33/2 = 346.5$ person-years.

In the second year of life, we begin with 330 ($363 - 33$) children remaining under observation from the preceding year; and during the year 3 new children are added, while 7 are withdrawn. Allowing $\frac{1}{2}$ year as the mean time spent in the household for each newly added person and each one withdrawn, the total life-experience in the second year, between the age-limits 1-2

$$3 - 7$$

years, is $330 + \frac{3 - 7}{2} = 328$.

In the same way, taking account of all additions and withdrawals, the life-experience in each successive year is summed up, until we have entered in the table a total of 378 individuals—the 363 present at birth plus 15 added at various times—of whom 91 have been withdrawn before reaching the age of 5 years, 31 by death and 60 for other reasons. In terms of person-years, where the unit is 1 person observed for 1 year, the aggregate life-experience between the age limits 0-5 years, is the sum of the five L_x values in the table, namely, 1,587 person-years. Within

this experience 31 deaths occurred, hence the *annual* death rate between the age-limits 0-5 years is: $31/1,587 \times 1,000 = 19.5$ per 1,000.

Table II, constructed by continuation of the process illustrated in Table I, shows the entire-life experience of the 794 present and former members of the 132 families at successive ages from infancy to old age. The aggregate is 9,671.5 person-years; and in each age class except the oldest, the experience comprises several hundred person-years. Opposite each age-group are set the deaths which occurred at that age, and the next column gives the annual death rate per 1,000 in the age class, calculated as the ratio of deaths to person-years. The last column shows, for comparison, the annual death rates at corresponding ages in the negro population of the state in 1920.

The death rates in the Kingsport families are approximately equal to those in the negro population of the whole state in the age group 1-19 years, and at ages over 50, but are very much below the state experience in the first year of life, and in adults aged 20-49 years. The low infant mortality in the Kingsport families is probably

TABLE III

MORBIDITY AND MORTALITY FROM TUBERCULOSIS IN NEGRO FAMILIES, KINGSPORT, BY AGE, TOGETHER WITH MORTALITY IN THE NEGRO POPULATION OF THE STATE, 1920

* From U. S. Mortality Statistics, 1920.

† Cases classed as "suspected" make up about one-third of the total.

due in part to the fact that the standard of living of the negroes in that city was well above the average; but it may be attributable in part to failure of informants to note some of the deaths of infants at very early ages, this being an error not unlikely to occur. The low mortality in adults aged 20-50 can hardly be attributable to any similar error. It more probably reflects the selective character of the life-table experience, which, being made up from the records of persons residing in established families, largely excludes certain classes of young adults suffering excessive mortality, namely, married couples of which both members have died young, residents of institutions, vagrants, and transients. With due regard to these considerations and to the small number observed, the agreement between the Kingsport mortality record and state-wide experience is close enough to indicate that the familial records are not grossly erroneous. At the same time, it needs to be clearly recognized that in certain important respects the method employed is selective with respect to mortality.

The 132 families furnished records of 27 deaths ascribed to tuberculosis. In addition to these, the clinic examinations revealed 50 more or less definitely diagnosed cases of pulmonary tuberculosis in living members of the families, making a total of 77 cases living and dead.* Distributing these 77 cases according to age at onset of illness—as nearly as this could be ascertained—and distributing the fatal cases according to age at death, age-specific annual morbidity and mortality rates are derived as shown in Table III, which also shows corresponding death rates in the negro population of the state. It will be observed that the tuberculosis mortality rates are very similar to those prevailing in the state at large, and that the morbidity rates, though much higher than usually shown in official records, are reasonable in relation to the mortality.

The foregoing tables of mortality and

* A majority of the 50 cases recorded in living members were judged to be inactive at the time of examination, and of these a considerable proportion were classed as "suspected." A reexamination of the suspected cases, which is now in progress, indicates that some 10 to 15 of this group may eventually be classified as negative, making a proportionate reduction in the morbidity rates of Tables III and IV.

morbidity in the whole group of families have been included only to illustrate the data and methods used and to check the reasonableness of the results (as to mortality), by comparison with current experience in the negro population of the state at large. We come now to the question of morbidity and mortality in familial contacts of known cases of tuberculosis.

came into household exposure subsequent to entry into the family.

When the population is thus subdivided, the numbers upon which age-specific rates must be calculated become so small that for significant comparisons it is necessary to summarize the results. For this the most convenient form is a statement of annual morbidity and mortality rates at all ages, adjusted to a

TABLE IV

MORBIDITY AND MORTALITY IN RELATION TO HISTORY OF FAMILIAL CONTACT WITH PULMONARY TUBERCULOSIS. NEGRO POPULATION, KINGSPORT, TENN.

| <i>Basis of Comparison</i> | <i>Contact history</i> | |
|----------------------------------|------------------------|-----------------|
| | <i>Positive</i> | <i>Negative</i> |
| Person-years in classification | 2,199 | 7,472.5 |
| Cases of tuberculosis: number | 26 | 51 |
| annual attack rate per 1,000 | 12.9 ± 1.7 | 6.8 ± 0.64 |
| Deaths from tuberculosis: number | 10 | 17 |
| annual death rate per 1,000 | 4.6 ± 1.01 | 2.3 ± 0.38 |
| Deaths, all causes: number | 28 | 68 |
| annual rate per 1,000 | 12.8 ± 1.62 | 9.2 ± 0.67 |

All morbidity and mortality rates adjusted to age-distribution of the entire life-experience in the whole group of 132 families.

Of the 794 persons included in the study, 299 gave a history of having been, at some time, in household contact with a case of certain or probable pulmonary tuberculosis. The mortality and morbidity rates in these known "contacts" subsequent to their exposure have been calculated by making up a life-table in which each contact is entered only for that period of his residence in the family after the known household exposure began, recording against this experience the subsequently observed mortality and morbidity.* As a control, a similar table has been made, dating from entry into the household, for all persons who gave no history of known household contact, plus the pre-exposure experience of those who

population of standard age-distribution. The comparisons made on this basis, in Table IV, indicate that the persons with a positive history of household contact suffered thereafter tuberculosis morbidity and mortality rates about double those of the control population, and in addition, suffered a materially higher mortality from other causes.

The figures given in Table IV show only the *average* morbidity and mortality risk for all familial contacts in this group of families, as measured by comparing their morbidity and mortality rates with those of a control drawn from the same universe. Given sufficiently extensive and exact data, it would be quite possible, by similar processes, to measure the variations in this risk as related to numerous circumstances which presumably are of importance, as, for instance, the age at which exposure first took place, its

* Where the known exposure occurred before entrance of the individual into the household in which he is listed, the post-contact life-experience is dated from entry into present household.

duration, the activity of the case to which the individual was exposed, parental history, etc. The number of persons included in this particular set of records is too small for such subdivisions as these more detailed studies would require and, indeed, is so small that no special significance should be attached to the result given as a measure even of the average risk to contacts in negro families. It is, however, of interest to note that the relative rates of mortality in the contact and control groups, respectively, are in reasonable agreement with the observations of Weinberg (1913, pp. 123-129) who, in his extensive study found that the children of tuberculous parents suffered rates of mortality (at ages under 20 years) from all causes about 1.28 times and from tuberculosis about 2.16 times the rates prevailing in the community at large.

It should perhaps be added, though it is sufficiently obvious, that in the procedure applied here, no attempt is made to distinguish between the risk resulting directly from exposure and that which may be due to constitutional weakness or generally unfavorable environment. These questions may be approached by the same general method, but require much more extensive data.

The method which has been described is in no sense new in its appli-

cation to studies of tuberculosis. It has been used by Elderton and Perry, in their studies of the mortality of persons treated in sanatoria; by Weinberg, in his excellent and extensive study of the mortality of children born of tuberculous parents; and by others. It appears, however, to have been applied little, if at all, to retrospective records of the kind here discussed; and since it is records of this character which are most readily available from the experience of public health organizations and clinics, it has appeared worth while to call attention to this general method for the study of material which at present too often remains unassembled.

Medical Examination of Domestic Servants*

CHARLES V. CRASTER, M.D., D.P.H., F.A.P.H.A.
Health Officer, Newark, N. J.

IN modern government the state has assumed the responsibility for the care of the indigent sick and has broadened many curative activities into real preventive measures. Thus we do not wait for epidemics to develop as a result of sewage contamination of our water supplies, or for cases of food poisoning to result from sophisticated or adulterated foods. The requiring of clean water, milk, and food supplies is as much a preventive activity as are the definitely preventive measures against diseases by inoculation or vaccination. It is such efforts to promote health that have called for the extension of safety devices into wider and wider channels of governmental control.

It required the wide public interest of the "Typhoid Mary" story to show the danger to individual households of an undetected typhoid carrier employed as a cook. The result of this publicity was the adoption by the New York Health Department of a requirement for the medical examination of food handlers. Dr. Louis I. Harris, the Health Commissioner, after 2 years' experience, made the following significant statement:

It is only a beginning, but one whose significance and ultimate possibilities may well be called impressive. The manifold benefits that may ultimately accrue from this system

must be left to the imagination of those who have glimpsed the possibilities of preventive medicine and especially of adult hygiene and periodical medical examination.

EXAMINATION OF FOOD HANDLERS STARTED IN 1920

This work, so well begun in New York, was adopted by Newark, N. J., in the middle of 1920, and since that time 150,000 examinations of food handlers have been made. The conditions encountered were tuberculosis, venereal disease, skin diseases, and various purulent conditions of the mouth, ear, and nose. During the 11 years the examinations have been carried on by the Newark Department of Health, there has been little or no opposition by the owners of restaurants and eating places, and we have received the full coöperation of the various labor unions. Even among the employees themselves it is not considered a hardship. The law acts as a bar to the employment of the sick and diseased, who would compete by accepting lower wages and longer hours.

Although the findings of the examinations for 11 years in Newark indicate that contagion is not more prevalent among the food handlers than any other body of industrial workers, the evidence gathered in the first few years showed that many were being employed when in the infective stages of tuberculosis. That this condition has been entirely

* Read before the Health Officers Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

eliminated is due undoubtedly to the semi-annual examination of food handlers. Skin diseases are rarely found among applicants; venereal diseases in the contagious state are frequently found.

There was observed even in the first few months of the procedure a remarkable improvement in the general appearance of food handlers. There was a more wide-awake and intelligent appearance in all of them, due evidently to the elimination of the cheap labor of diseased persons previously engaged in other occupations who had sought the lighter and more elastic hours of restaurants and lunch counters. This is particularly important among the food-handling class for the reason that many are part-time workers, frequently recruited from married women and mothers of families who have some part of the day at their disposal.

SINCE 1930 DOMESTIC EMPLOYEES HAVE BEEN EXAMINED

The situation with regard to food handlers being adequately taken care of, the attention of the department was directed to the number of domestic employees attending the various clinics of the City Dispensary. Many of these were listed as tuberculous; others as suffering from venereal diseases in various stages of infectivity. The domestic servant by the nature of his or her employment was considered to be even more directly in contact with the family circle of the householder than the restaurant food handler. Some of them, such as nurse maids, take care of very young children, and their freedom from contagious disease is a matter of supreme importance. Others, such as cooks, waitresses, maids, laundresses, and chauffeurs, have not so direct contact with individuals, but none the less it is important to the family that no contagious diseases should exist among them.

TYPE OF EXAMINATION

The ordinance requiring the medical examination of domestic employees was passed in September, 1930. It requires all domestic employees to file with the Department of Health a certificate from a duly licensed physician setting forth that such persons are free from tuberculosis, and any other contagious or communicable disease. The certificate has to be made upon blanks supplied by the department, and is good for a period of 6 months. Provision was made for a free examination at the department clinics. After the examination a domestic servant's card is issued bearing a photograph of the applicant. The penalty for failure to comply is a fine of \$25 for the first offense and \$50 for the second. Both the domestic and the employer are liable under the law for any violation of the ordinance.

The number of domestics employed in Newark, according to the U. S. Census for 1930, was: males, 3,864; females, 9,674; total, 13,538. The group included under hotel and restaurant help are food handlers generally and are not purely domestic in nature. It was considered that the census figures overstated considerably at this time the number of individuals employed in the domestic group. This was verified by a house-to-house canvass of the residential districts, where it was found that owing to the business depression families were either doing without domestic help or had considerably reduced the number of servants employed.

The enforcement of the domestic servants ordinance was placed in the division of sanitation. The actual examinations are conducted in the dispensary clinics under the supervision of the bureau of tuberculosis. The form of examination carried out is similar to that for food handlers, and includes examination of the skin to detect diseases such as eczema, psoriasis, abscesses, cuts and wounds. The at-

tention of the examiner is directed to the possible association of skin diseases with syphilis. When such is suspected, a Wassermann blood test is required.

The examination of the chest must include all known procedures for the determination of chronic pulmonary diseases. Any abnormal chest condition found is sufficient cause for rejecting the applicant pending X-ray or fluoroscopic examination.

The examination of the nose, mouth, teeth, throat, ears, and eyes is directed toward the discovery of acute or chronic conditions of an infectious nature. Especially where there is a discharge, swabs are taken for examination.

Blood tests are required where there is a history of typhoid fever or syphilis. When there is no scar, vaccination against smallpox is required.

In the examination for venereal disease in the case of males a routine inspection of the sexual organs is required. Where suspicious sores or discharges are present, swabs are taken for dark-field examination and blood for a Wassermann. For women, there is required a statement from each applicant of freedom from venereal disease.

DOMESTIC EMPLOYEE'S CARD

After examination the applicant, if approved, takes the history card to the sanitary division, where a domestic servant card is issued bearing a photograph of the individual. Where there is doubt as to diagnosis for any reason whatsoever, the applicant is given a reëxamination slip and a temporary card. This is usually for a week or a month. When an applicant is rejected the physician notifies the sanitary division, which in turn notifies the employer and employee in writing. The cause for the rejection is never given to the employer.

As is the case with all new laws, a considerable amount of education and publicity was required. All employ-

ment agencies, public and private, were brought into the department for a conference. The new ordinance was explained and it was pointed out that no domestic employee should be placed in any position without possessing the domestic employee's card. Local newspapers carried copies of the new ordinance displayed above help wanted advertisements. Domestics advertising for places were mailed copies of the law with instructions for examination. All hotels, clubs, lodging houses, and institutions were canvassed and their domestics sent down for examination. A house-to-house canvass was carried out in the residential districts and all householders were duly informed of the new ordinance.

During the year 1931 the law was not generally known to the public and the follow-up system had not been sufficiently organized. More definite efforts in the early part of 1932 produced better results. The number of examinations to date follows. It will be observed that there were over 10,000 examinations during first 8 months this year compared to 2,863 during 1931.

INFECTIONS FOUND

As a result of clinical examinations and a check-up of domestics attending the venereal disease clinics the following figures were obtained: syphilis in all forms 115, positive Wassermann 52, negative Wassermans 63. Among the group found infected with syphilis 66 were day workers, the remainder domestics in various lines of employment.

There were 39 cases of skin diseases reported. These included impetigo, scabies, seborrhea, acne vulgaris, psoriasis, and purpura.

Among the 34 cases of tuberculosis found 14 discontinued work, 8 moved and could not be traced, 5 were sent to sanatoria, 4 in arrested stage were allowed to work, 1 died, 1 worked outside the city, 1 left for his home in the South; 25 were colored and 9 white.

The Newark ordinance did not specify that the domestic suffering from a contagious disease had to be in the communicable stage to be excluded from employment. It is assumed, however, that this was the intent of the ordinance, and therefore domestics with arrested tuberculosis or with venereal disease in a non-communicable form are allowed to continue in their occupation. With regard to those with diseases in the communicable state, the applicant is refused permission to continue in employment and the employer so informed. The department follows up all applicants who have been found infected, to see that proper treatment is being carried out. By the city ordinance we cannot divulge the nature of the disease to the employer. This is better for the self respect of the domestic and insures greater effort in bringing about proper and continuous treatment.

A PRACTICAL METHOD OF SAFEGUARDING THE FAMILY

I am asked repeatedly, "Is the examination of food handlers and domestics possible for small communities in the light of the cost for specialized service?" The answer will depend upon whether a complete medical examination is contemplated, as in

the case of life insurance companies, or an examination for contagiousness only. If the latter, the necessary examination is not so extensive and can readily be carried out by a well equipped physician in a few minutes for each applicant. Blood tests and X-ray work will require of course longer.

Routine Wassermanns and X-ray examinations are not made as yet unless symptoms indicate their necessity. Among certain groups of domestics, such as the day workers, the taking of a routine blood test might be of advantage. In fact, we are to start making Kline tests in certain groups of domestics within a few weeks, as our Law Department is of the opinion that it is satisfactory, providing applicant signs a routine permission form. The same may be said of the need for a mental or intelligence test. This might be a good procedure for those in charge of babies and children when quick thinking is sometimes a necessity to avoid accidents or the doing of things that might be hazardous to the lives of little ones. From the venereal disease standpoint, vaginal smears are to be taken from this particular group of baby nursemaids.

From the viewpoint of preventive medicine, there can be little doubt that the examination of food handlers has served as a useful and continuous aid in our campaign for cleaner foods. Its extension to domestic employees seems a well worthwhile activity, having as its object the exclusion from the homes of our people of those with contagious diseases.

Sunlight and Health*

HAVEN EMERSON, M.D., F.A.P.H.A. (*Life Member*)

Professor of Public Health Practice, Columbia University, New York, N. Y.

THE heretic Pharaoh Akhnaton, about 3,290 years ago, insisted that there was only one God, one source of all goodness and life, the Sun. He has had many successors and he was doubtless preceded by religious worshippers of light or heat from the Sun. His disciples are found among the heliotherapists today and it behooves us to speak cautiously when in the presence of such enthusiasts.

We know that sunlight was used in the treatment of disease by Hippocrates at Cos, and by the Priests of Aesculapius at Epidaurus. The interest of modern medicine with the use of light in treating disease began seriously with the work of Finsen in 1893, who cured lupus by localizing the light rays of the sun, after filtering out the heat rays. It is by raising the local and general resistance, not by destroying the tubercle bacillus in the skin that ultra-violet rays cure lupus. Ten years later (1903), Rollier started his sunlight treatment of surgical tuberculosis in Switzerland.

The relation of the lack of sunlight to the etiology of disease was first described by Palm, an English physician, in 1890, when he attributed rickets to insufficient sunlight, noted the seasonal incidence of the disease, and described its prevention and treatment by the use of sunlight.

An abundant literature has developed on the known and imagined relationships between sunlight and health and mortality, and the therapeutic application of part or all of the radiant energy of the sun in preventing and treating symptoms and persons.

As a factor in the environment of man, of the deepest and probably, biologically speaking, most ancient significance, sunlight as the indispensable cause of the growth of green plants, and as a condition without which man cannot retain health or continuously reproduce his kind has an importance which increases steadily with man's persistent complication of housing in the interest of his physical comfort and convenience.

May I assume that you are at the moment less concerned with light as a resource in the treatment of disease, than in evidence or accepted opinion as to the preventable conditions resulting from too much, or not enough, sunlight.

Excess of sunlight is known to cause two types of disturbance, physical lassitude, and nervous irritability, the former apparently due to the heat, the latter to the light radiations particularly. Insolation or "sunstroke" may be produced by excessive heat in the absence of sunlight.

In southern Arabia, in our own deserts, and in the tropics of several continents, man's survival has always depended upon his sheltering himself from the heat of the sun, even when his skin is by adaptation capable of pro-

* Read at a Joint Session of the Public Health Engineering and Industrial Hygiene Sections of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

tecting him against the over-stimulation of the light rays. In temperate climates, the injudicious sudden or extreme exposure of white skinned persons, especially of children and thin blond persons, to midsummer sun, even when not to a degree to cause sunburn or to damage from heat, not uncommonly causes irritability, sleeplessness, loss of weight, and a variety of nervous phenomena of similar character. Snow blindness from excess of ultra-violet light and its reflection may follow excessive exposure to sunlight in high altitudes in any climatic belt.

In the treatment of surgical tuberculosis in white skinned people the benefit seems to be in proportion to the pigmentation of exposed skin.

Insufficient sunlight, which we can fairly assume need not, or does not, occur ordinarily in the tropics, but is common at part or all times of the year in temperate or polar regions, is responsible for only one clearly defined clinical entity, rickets.

The cause of rickets in its full complexity is not yet known, but it appears that the growing child from the antenatal period to the age of 2 to 3 years cannot accomplish sound development of bone unless the calcium and phosphorus metabolism has the benefit of the stimulation which sunlight gives to the ergosterol in the skin cells.

The small amount of ultra-violet radiations that penetrates the ozone of our atmosphere is apparently indispensable to the normal development of bone of man and other mammals, unless its equivalent is artificially supplied by other means (cod liver oil, radiated oils, egg yolks, etc.).

Nothing is plainer in the morbidity and mortality experience of our northern cities than that the presence of rickets contributes heavily to sickness and death from bronchitis and pneumonia in young children, to lowered resistance to measles, whooping cough,

and tuberculosis, and more remotely, by reason of pelvic deformities, to maternal deaths from difficult, instrumental, or operative deliveries. A further serious by-product of rickets is the disturbance of dentition, and a greater susceptibility to caries and malocclusion of the jaws. Spasmodophilia is another condition closely related to rickets and due to insufficient sunlight for healthy infancy. It is to be remembered that rickets is a general metabolic disorder affecting other tissues than the growing ends of the bones, particularly the voluntary musculature and the blood.

It may well be that the growth and development of children and adults suffers disadvantage from insufficient sunshine or skyshine in other still unrecognized ways, but at least there is no other disease entity now described which is believed to be due to such insufficiency. Wise feeding alone will not prevent rickets in the absence of sunlight unless a substitute for solar radiation is added. The same action that determines the prevention of rickets is seen to act in assisting the repair of bone, whether this be in the callus of a fracture or in a bone diseased with tuberculosis.

There are psychological values in sunshine well recognized in the treatment of disease, and particularly in the management of chronic and convalescent patients, and it may fairly be assumed that the delight in the presence of sunlight, indoors and out, from infancy to old age, which is quite universal, is based on physiological benefits, whether they be because of warmth, dryness, ease of work, wider range of pleasures, range of color and form to delight the eye, or the feeling of euphoria that mankind gets from having his place in the sun. Sunlight assists in the healing of wounds on the surface of the body, relieves some of the pain of damaged tissues, and im-

proves the bactericidal properties of the skin in and about the wound.

Apart from these subjective, personal, bodily and spiritual relations of sunlight to health there are the objective or environmental effects of sunlight upon which some of man's safety from his biological enemies depends.

Sunlight and skylight in proportion to their intensity and duration will sterilize surfaces exposed to them, and will even penetrate with bactericidal effect into the unbroken skin, only a fraction of a millimeter in the normal blood-filled tissue, but as far as 4.25 mm. into the skin made anemic by pressure.

This bactericidal effect, which is greatly reduced when radiations must pass through ordinary window glass obliquely into a room, is by a direct action on the cells, and not by the intermediate development of hydrogen peroxide or other chemical, and it is due to the photo-chemical capacity of the cell to absorb ultra-violet rays. In addition to this effect bacteria may be destroyed by the dehydration and oxidation caused by the heat rays of the sun.

Perhaps the most important problem of environment in city housing in northern climates is provision for sufficient light, direct or diffused, from sun or sky, to maintain reasonable sanitation of rooms and halls through the disinfectant property of light, which if not hindered by curtains and dirty glass will accomplish much to reduce viability and virulence of the common human pathogens.

Cloudiness, fog, smoke, or dusts, or combinations of these reduce radiant energy of sunlight below a point safe for the sanitation of the home or for the growth and development of infants. The main factor in determining the effectiveness of ultra-violet solar radiations in benefiting human health is the thickness and quality of the atmospheric

envelope and the angle of incidence of the rays. Sunlight is much less controllable for selective therapeutic effect than are artificial radiations under many urban conditions of climate, smoke, etc.

The long red and infra-red rays have effects upon the skin even when they are not appreciated by the eye as light. There has been recent suggestion offered by Leonard Hill of London to the effect that there are selective effects of some of these long infra-red rays coming from an open fire or incandescent gas heater or dark electric radiating heater plate which favorably affect the mucous membrane of the nose and throat by reducing turgescence, and tend to prevent colds. This suggestion will need much confirmation before it can be accepted. Light baths if carried with discretion to the point of erythema may increase general resistance to infection, an effect which can be produced also by heat of various origins, or by a mustard plaster.

There are 3 indices of measurement for therapeutic strength of ultra-violet rays: (a) lethal effect on infusoria; (b) erythema of the skin; (c) bleaching of a solution of acetone and methylene blue. This bleaching may be repeated as much as 41 times in a day in the Alps, although it may take place only once or twice in a day in England in the winter.

The total ultra-violet radiation from the sky exceeds that which comes directly from the sun. The sun at the zenith gives but 90 per cent of the total sky shine coming from blue sky.

Man's eyes suffer, and his effectiveness in near and far vision work is reduced when artificial light falls too far below the quantity and quality of sunlight. It is to sunlight that our eyes are biologically best adapted.

Studies have been made in an effort to support our physiological evidence of the benefit to health from sunlight, by

proof of correlation between lack of sunlight and higher sickness and death rates. There are so many complicating economic, social, educational, and racial factors involved in comparing neighborhood or district death rates, on a basis of the amount of soot-fall, or on the quantitative presence of ultra-violet rays, that unequivocal evidence as sought has not yet been found, although the opinion is widely held that dark, smoky, foggy local atmospheres actually do cause a rise of local death rates. Certainly in London the presence of serious fog always causes a rise in deaths from respiratory, circulatory, and infectious diseases, and from accidents.

When the air is dirty or smoky, cleanliness and window ventilation are discouraged, light is reduced, plant life is damaged, spirits are depressed, and vitality is lowered.

DEATH RATES PER 100,000 PERSONS OF BOTH SEXES, AGE 10-19, PER ANNUM, FROM ORGANIC HEART DISEASE, 1916-1921, INCLUSIVE

| | | | |
|--------------|------|------------|------|
| Boston | 7.03 | Chicago | 6.19 |
| New York | 5.42 | Detroit | 4.76 |
| Philadelphia | 5.38 | Cleveland | 4.42 |
| Richmond | 2.88 | Cincinnati | 3.55 |
| Atlanta | 1.92 | Birmingham | 1.67 |

I am privileged to add here the provisional results of a study of the death rates from organic heart disease (rheumatic carditis) occurring in the age decade 10 to 19 years, in cities in this

country, according to latitude and smokiness of atmosphere, from an unpublished report from the Department of Sanitary Science at the College of Physicians and Surgeons of Columbia University.

As one follows the coast cities south from Boston to Atlanta he finds a falling organic heart disease death rate in those 10 to 19 years of age, from 7.03 per 100,000 per annum in Boston, to 1.92 in Atlanta.

Similarly in following soft-coal cities of the country from Chicago south to Birmingham, one finds a fall in the rate from 6.19 in Chicago to 1.67 in Birmingham.

Many factors, and possibly fallacies, need consideration before accepting this as evidence that the changes in these death rates are related to climatic differences in ultra-violet radiations, which may cause differences in the virus of rheumatic fever or variations in the resistance of youth to this infection.

We need studies of this kind. We need animal experimentation to supplement domestic and clinical observations, to supplement and correct our present convictions that sunlight, sunheat, and skylight have indispensable values to health and disease prevention which cannot safely be ignored, and for the preservation of which we are well justified in taking administrative action in the matters of housing and air purity, particularly in our northern cities.

Health Problems Peculiar to the Southern States*

JOHN A. FERRELL, M.D., DR.P.H., F.A.P.H.A. (*Life Member*)

Associate Director of the International Health Division of the Rockefeller Foundation, New York, N. Y.

THE region known as the "southern states," according to the boundaries established by the Southern Medical Association, embraces 16 states and one-third of the population of the United States. In 1930 the residents of this area numbered 40,761,751, of whom 30,513,518 (75.9 per cent) were white; 9,420,880 (23.1 per cent) colored; 702,988 (1.7 per cent) Mexican; 117,369 (0.3 per cent) Indian; and 7,356 (0.02 per cent) Japanese or other orientals. This vast region consisting of 945,028 square miles, or approximately 32 per cent of the total area of the United States, lies mainly in the north temperate zone, but the five gulf coast states lie partly in the subtropical zone. Because of the location and climate of this section and its commerce with tropical countries and air service from them, the inhabitants are more exposed to tropical diseases than are residents in the northern states.

The history of the South, especially in regard to settlement, the Civil War, and the Reconstruction Period, as well as its agriculture and its large negro population, has given rise to the opinion now commonly held that it is a distinct region, having common interests, advantages, and problems. The progress of public health in this region has been influenced by the development

of its political, educational, and social institutions, and by economic conditions. Prior to the Civil War, the general standard of living, except among the plantation owners, was low. The four years of Civil War and the subsequent years of misrule during the Reconstruction Period left the South prostrate and poverty stricken. The sickness and death rates were known to be high, but their exact levels were not uniformly recorded. During the last decade of the 19th century the South began to emerge into a new and brighter era. Leaders appeared to give guidance in bettering economic conditions, in improving agricultural methods, in developing the public school system, in building roads, and in furthering other progressive movements. Each of these advancements had a bearing on the public health, but as a distinct movement in itself, public health made very little, if any, progress until the 20th century was under way.

When the Rockefeller Sanitary Commission was organized in 1909 to combat hookworm disease in the South, the states of Maryland, North Carolina, Virginia, and Florida had recently appointed full-time state health officers, and such cities as Baltimore, Richmond, Savannah, and Jacksonville had developed health services creditable for that period. In general, however, the states, cities, and counties of the South, prior to 1910 did not have any real health service, although part-time

* Presented before the Southern Branch American Public Health Association at Birmingham, Ala., November 14, 1932.

physicians may have been employed by state and local governments during epidemic outbreaks. The coöperation of the Rockefeller Sanitary Commission with the states of the South gave impetus to the health movement. The \$1,000,000 donation of Mr. Rockefeller to combat hookworm disease was expended in 12 southern states during the years 1910-1915. It made it possible for each state department of health to have from 4 to 6 full-time health officers with laboratory assistants who conducted clinics and educational work throughout the states. The accomplishments against hookworm disease and soil pollution made public health history and incidentally created a popular desire for a creditable and continuous health service. At the same time the state health departments were being organized and strengthened. Their work was placed on a full-time basis in practically all southern states and divisions for diagnostic laboratory service, communicable disease control, vital statistics, and sanitary engineering were created and financed by legislative action.

Beginning with the admission of Maryland into the U. S. Registration Area for deaths in 1906, followed by the admission of Kentucky and Missouri in 1911, and Virginia in 1913, the movement for the improvement of vital statistics records has finally brought into this area all the southern states except Texas. This state will no doubt be admitted in due course. The New England states, Michigan, Indiana, and the District of Columbia, which comprised the original registration area, had been admitted by 1900. Only in the past ten years or less, therefore, has it been possible to compare the general and specific causes of death in the southern states with similar records for other sections of the country.

While the state health organizations were gaining strength, full-time county

and city health departments were being developed in the southern states. In 1915, of the 14 full-time county health departments operating in the United States, 11 were located in the South: 1 in Kentucky, 2 in Alabama, 2 in Georgia, and 6 in North Carolina. At the close of 1931, of the 596 full-time county health organizations in 36 states, 451 were located in the 16 southern states, serving more than 17,000,000 inhabitants, or approximately 43 per cent of the total population of this section. The U. S. Public Health Service, the Rockefeller Foundation, and other extra-state health agencies supported this movement. Although in the South the health movement was slower in starting and was confronted with greater difficulties and more serious problems than in other sections of the country, it developed more rapidly there in the past 20 years than elsewhere in the United States.

Public health work, we are confident, has greatly improved the health status of the people of the South, but owing to lack of complete records, except for recent years, we cannot accurately determine the extent of the improvement. Table I compares the average death rates for 1929, the latest published figures, of whites and negroes separately for 34 causes of death in 14 southern states with the rates in 8 northern states. In the columns to the right are shown the comparative averages for 14 states. If the average death rate for the southern white population be regarded as "1" (see column A), then the rates for the southern colored population would be the figures in the second column, B, and those for the northern states the figures shown in the last column, C. A study of the table reveals that in the South the negro rates are markedly higher than the white rates for syphilis, homicide, gonococcal infections, and pellagra, and considerably higher for pulmonary and

Note: 14 Southern States: Ala., Ark., Fla., Ga., Ky., La., Md., Miss., Mo., N. C., Okla., S. C., Tenn., Va.
8 Northern States: Calif., Ill., Mass., Mich., N. Y., Ohio, Pa., Wash.

Averages are the means of individual states' rates.

U. S. Bureau of Census figures for 1929—Table prepared by Hugo Muench, M.D., Statistician and Staff Member of (I. H. D.) Rockefeller Foundation.

other forms of tuberculosis, as well as for tetanus, typhoid and paratyphoid fever, malaria, whooping cough, and puerperal causes. The negro rate is markedly lower than that of the whites

of the South for scarlet fever, suicide, erysipelas, rabies, lethargic encephalitis; noticeably lower for measles and diphtheria, and lower to a less degree for tabes dorsalis, poliomyelitis, cerebro-

spinal meningitis, exophthalmic goiter, cancer, and diabetes.

The death rates for southern whites are markedly higher than those for the population of the northern group of states, for malaria, pellagra, dysentery, typhoid and paratyphoid fevers; considerably higher for rabies, influenza, tetanus, whooping cough, and diphtheria; and higher but to a less degree for poliomyelitis, diarrhea and enteritis in children under 2 years of age, homicide, chronic nephritis, and puerperal causes. The rates for the general population of the northern group of states are appreciably higher than those for the southern whites for exophthalmic goiter, cerebrospinal meningitis, and alcoholism; and higher but to a less degree for syphilis, tuberculosis, diabetes, lethargic encephalitis, suicide, cancer, lobar pneumonia, erysipelas, measles, tabes dorsalis, gonococcal infections, accident, scarlet fever, cerebral hemorrhage, and diseases of early infancy.

Although the North has its excessive death rate from exophthalmic goiter and cerebrospinal meningitis, the South has its excessive rates among whites from malaria, pellagra, and typhoid. In general, however, the death rates among the southern whites compare favorably with the rates in other parts of the country. The negro death rates are generally exceptionally high and as a result have raised the average rates for many causes of death for the South.

The rate of growth in public health expenditures has been more rapid in the South than elsewhere in the United States during the past 20 years. This is all the more striking when it is realized that the average per capita wealth in the southern states * ranges from \$1,284 to \$3,196, and the average per capita income † from \$248 to \$653, as compared with 8 northern states (see Table I, footnote) for which the per

capita wealth * ranges from \$2,880 to \$3,725, and the per capita income † from \$661 to \$1,158.

The growth in public health expenditures can be illustrated by the fact that the health appropriations in the 11 southern states originally aided by the Rockefeller Sanitary Commission had increased from \$225,395 in 1910 to \$3,845,580 in 1930, or 1,600 per cent. The legislatures of Alabama and Virginia each appropriated in 1930 more than twice as much money for public health work as did the 11 southern states combined in 1910.

The question naturally arises as to whether or not there has been a larger reduction of the death rates for controllable diseases in the South than in the North. If the answer should be based upon the percentage of reduction, the showing for the South in general would not be as favorable as for the North. The objection to a percentage basis is that it gives no idea as to the number of lives saved. For example, if a state has 3,000 deaths from a certain disease, it must reduce the number by 1,500 in order to have a 50 per cent reduction, whereas another state having only 4 deaths from the disease could, by a reduction of 2 deaths, show a 50 per cent reduction. A comparison based upon the change in the mortality rates indicates more accurately, we believe, the relative progress, because it reflects the number of lives saved. Table II compares the average mortality per 100,000 population for a 9-year period, 1921-1929, in 10 southern states, with the average change for the same period for either the original registration area, or the U. S. Registration Area. It will be noted that, with very few exceptions, the reductions in death rates in the 10 southern states exceed those in the

* Figures are from *The National Market*, Crowell Publishing Co., 1926.

† Figures are for the year 1928 as published in the *World Almanac* (1931).

control areas for typhoid fever, malaria, and tuberculosis.

Aside from the influence of the negro on health problems in the South, there are, of course, certain important diseases that are peculiar to this region. One of these is hookworm disease. Through the intensive measures directed against this infection during the period 1910-1915, its prevalence and severity have diminished. The subsequent continuation of treatment and the intensive work in rural sanitation have further limited the disease, but there are still sections in the South where little has been done and where the clinical disease is still found. Formerly it was customary to make the diagnosis of hookworm disease when persons

were found to harbor hookworms, regardless of whether or not clinical symptoms were manifested. Furthermore, the assumption was that in the absence of adequate sanitary facilities, any person who deposited hookworm ova on the soil was a menace. In more recent years the students of this disease have made a distinction between infestations causing illness and those resulting in a carrier state only. Certain soils have been found to be unsuited to the development or survival of hookworm larvae. These developments have led to some misunderstanding as to the character and importance of the present residue of the disease in the South. As the disease is seldom given as the cause of death, it

Notes: This represents the average annual change in actual deaths per population, as obtained by fitting a trend line to the years in question.

O. R. S.—Original registration states, all in the North.

U. S. R. A.—Entire registration area, including southern states.

Table prepared by Hugo Muench, M.D., Statistician and Staff Member of (I. H. D.) Rockefeller Foundation.

is not possible to ascertain its exact status in any community, except by surveys involving the examination of samples of the population. Fortunately quite a number of such surveys have been made from time to time in typical counties, and as a rule they show that hookworm disease is gradually diminishing in prevalence and in severity. A number of surveys of Mississippi counties are being made this year.

Malaria in the past has been widespread in the United States, occurring in such states as New York, Ohio, Michigan, and Iowa; but with the clearing and cultivation of the land, and improved drainage, this disease has gradually receded southward, so that its prevalence now is limited essentially to the southern states. In towns and cities of this section it is, as a rule, under control, but in certain rural areas it is still a real health problem. Its prevalence varies from year to year with the amount and character of precipitation in the spring and summer months. The *Anopheles quadrimaculatus* is the only vector of malaria of importance in the South. The habits of this mosquito are better understood than formerly, likewise knowledge as to practical control measures is more definite than in the past, so that we are better prepared than formerly to combat the disease.

Pellagra, it will be noted from Table I, is practically absent from the northern group of states, but in the South the death rate for this disease among the whites is 11.61 per 100,000 population, and among the negroes, 39.47. Its occurrence generally seems to be associated with low standards of living, including a lack of certain essential foods. Through the researches of Goldberger of the U. S. Public Health Service and others, practical methods for combating the disease are now known, and in varying degrees are being

applied. In 1929, there were 6,621 deaths from pellagra in the registration area; 70 per cent of them occurred in 6 states—North Carolina, South Carolina, Georgia, Mississippi, Alabama, and Arkansas (Table III).

Typhoid fever is not peculiar to the South. Epidemics have occurred in recent years in northern states and in Canada, but from the standpoint of prevalence and death rate, the disease is far more a problem in the South than in the North. By reference to Table I, it will be noted that the typhoid death rate for the southern states among the whites is nearly 4 times that for the northern group of states, and among the colored population more than 9 times as great. Surveys made in recent years have shown that the greatest prevalence of typhoid in the South is in small towns which are not adequately sewered or otherwise sanitized. Typhoid surveys in the South were begun by the U. S. Public Health Service about 1911, while the hookworm campaign was under way. The forces engaged in activities against both diseases found common ground in the improvement of rural sanitation and in the establishment of full-time county health organizations. The building of sanitary toilets was the initial activity of many of the full-time county health departments that have been established in the South. It is interesting to note from Table II that the average reduction in typhoid for the past 9 years in each of the 10 states listed is somewhat greater than in the northern states composing the original registration area. The fact remains, however, as indicated by the rates for 1929 shown in Table I, that the disease is still a serious health problem in the South, demanding better methods for disposal of excreta, further improvement in water and milk supplies, and further protection against human carriers and flies and other insects which may carry the disease.

Tuberculosis presents a problem of great magnitude among the negroes in the southern states. As shown in Table I, the average death rate for pulmonary tuberculosis in 1929 among the colored population of the South was 155.37 per 100,000. In comparison with this, the average rate for all races

in 8 northern states was 64.62, and for the white race in the southern states 52.87. The status of the southern whites with regard to pulmonary tuberculosis would appear, therefore, to be more satisfactory than that of the general population in the North. The picture is markedly different for the negroes in the South, and this is true for all other forms of tuberculosis as well. That progress is being made in the suppression of tuberculosis is indicated in Table II. During the period between 1921 and 1929 the average annual change in mortality due to all forms of the disease has shown improvement, and this change has been more marked for a number of the southern states than for the states composing the original registration area. It is obvious, however, that much remains to be accomplished in the suppression of this disease among the negroes of the South and that the solution of the problem should continue to receive the most careful consideration of the public health workers of this region.

Dengue (Table IV), like hookworm disease, does not stand out in the mortality tables, but from time to time it becomes epidemic in the southern states, as in 1922 when it caused 548 deaths in nine southern states. The number of deaths does not reflect the widespread sickness and disability, the serious impairment of the physical efficiency of thousands, and the crippling of agriculture, industry, and commerce, that result from a dengue epidemic. As yellow fever is spread by the mosquito *Aedes aegypti*, which is also the vector of dengue, and as almost the entire population of the United States is non-immune to yellow fever, the introduction of the disease from South America into the southern states must be considered as a possibility. The last epidemic of yellow fever in this country occurred in 1905. It was almost completely confined to New Orleans, in which city there were 434 deaths in that year.

Endemic typhus is also to be reckoned with in the southern states, where the disease is apparently on the

increase. In 1929 it caused 11 deaths in Alabama and during the first 6 months of 1932, 200 cases were reported to the U. S. Public Health Service from Alabama and Georgia; 125 of these cases occurred in Alabama, where there were 5 deaths. It has been found by officers of the U. S. Public Health Service that the important vector of the disease in the southern states is the rat flea. The situation is sufficiently important to call for prompt attention.

SUMMARY

The South has made rapid progress in the field of public health. The negro is responsible for death rates in the South that are considerably higher than the death rates in other sections of the country. Any program for the improvement of health and the lowering of

death rates in the South must afford the negro health protection. For the whole population in general, and the negro in particular, intensive public health measures should be carried on to combat such diseases as syphilis, pellagra, malaria, typhoid, tetanus, whooping cough, diarrhea and enteritis in children under 2 years of age, and other diseases which still cause high death rates. That progress has been made in the control of certain diseases in the South is reflected by the figures in Table II.

In the solution of health problems peculiar to the southern states, it is fortunate that those interested in and engaged in public health service in this section of the country can meet together and exchange ideas and experiences and plan for more effective and more concerted action against the common enemy, disease.

Undulant Fever

A STUDY¹ recently carried out in Ontario is not only interesting in itself, but almost more so in the implications involved.

In a hospital for epileptics where the patients were supplied with milk from a herd belonging to the hospital and known to be infected with contagious abortion, 100 patients were tested by the agglutination test, as well as the skin reaction. Under the first test, 63 showed a positive agglutination reaction, in 23 of whom the dilution was 1 to 80 or greater. The intradermal skin reaction was positive in 45, in 7 of whom it was weak, in 19 moderate, and in 19 strong. Clinically, 26 had fever, usually of the undulant type, the average peak being about 100° F. Sixteen were definitely underweight,

running from 20 to 30 lb., while 3 showed enlargement of the spleen, and 2 tenderness in the splenic area.

The authors concluded that 22 per cent gave evidence of active infection, 38 per cent of past infection, and 40 per cent no evidence of infection. While the authors content themselves with commenting upon the value of laboratory tests in general, and the intradermal skin test in particular, some commentators hold that the results indicate that the *Br. abortus* may not only cause the typical fever associated with it, but also may give rise to latent and subclinical infections not usually recognized as types of undulant fever.

Industry in Medicine*

C.-E. A. WINSLOW, DR.P.H., F.A.P.H.A. (*Life Member*)

Professor of Public Health, Yale School of Medicine, New Haven, Conn.

THE problems with which this section of our Association deals are, for the most part, properly comprised under the title of "Medicine in Industry." If we use the term "medicine" in a broad sense to include the allied sciences of hygiene and sanitation, we are here chiefly concerned with the direct applications of medicine to the safeguarding of industrial tasks and the promotion of industrial efficiency. In the pursuance of such purely industrial aims, however, the scope of services rendered has broadened to an astonishing degree. In many instances the development has gone so far as to transcend the primary concept of a service rendered by medicine to industry. In such cases it would be more accurate to say that industry is serving the broad cause of medicine as a whole since it is providing medical care of unusual quality and under peculiarly favorable conditions not only to industrial employees but to their families as well and sometimes to the entire populations of the communities concerned. It is with such extensions of industrial health services that I propose to deal briefly; and I have chosen the title "Industry in Medicine" to indicate the change of emphasis with which I am concerned.

In general, it may fairly be said that the major stimulus for the development

of industrial medical services in the United States has come from the Workmen's Compensation Acts. The physician was first brought into the factory to care for industrial injuries and thus to minimize compensation costs. Once in the employ of industry, however, he found many other things to do. The care of compensable injuries led on to the care of ambulant cases of non-compensable illness, to periodic health examinations, to sanitary control of industrial processes, and to hygienic supervision of the life of employees. The National Industrial Conference Board in its last report¹ lists the objectives and activities of the medical department in the following inclusive terms:

The following points have been indicated as the foremost objectives of industrial medicine:

1. To place individuals in the work for which they are best fitted
2. To procure and maintain fitness for work
3. To educate the worker in personal hygiene and the prevention of accidents
4. To reduce loss of time, absenteeism, and short work spans

In attaining these objectives medical departments in industry are found to be engaged in the following activities:

1. Physical examinations of:
 - a. Applicants for positions
 - b. Those who have been absent because of illness, upon their return to work
 - c. Employees who are being transferred from one department to another
 - d. Employees to be promoted to more important positions
 - e. Those engaged in occupations hazardous to their health or the safety of others
 - f. Those who have defects that should be followed up

* Read before the Industrial Hygiene Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

- g. Older workers
- h. All workers in a general program of health promotion
- 2. Diagnosis and treatment of injuries resulting from accidents that occur during working hours
- 3. Diagnosis and occasionally treatment of surgical conditions not resultant from working conditions.
- 4. Diagnosis and treatment of minor illnesses. These are treated usually only so long as the employee is able to come to the plant dispensary or hospital.
- 5. Assistance, chiefly through advice, in obtaining proper care outside the plant for cases of a more serious nature, or those for which there are no facilities in the medical department. This entails coöperation with the family physicians of employees and with local health organizations, clinics, and specialists. Medical supervision can act as a general clearing house for all matters in reference to medical care of employees.
- 6. Education of the worker in safety practices, personal hygiene, and health habits.
- 7. Supervision of sanitation, illumination, ventilation, and all other working conditions that affect health, with special attention to occupational disease hazards.
- 8. Research.
- 9. Occasionally, insurance and compensation adjustment.

It is important, I think, in dealing with activities which are expanding so greatly, to consider with some care the underlying principles which justify their existence and which should govern their development. I take it that there are essentially two such principles.

First, the employer has a moral (and often a legal) responsibility to protect his employees against any special hazards to health which are inherent in a particular industry. Measures of this type are not matters of choice, but essential and inalienable duties. Under this heading come such services as the following: safety engineering such as will offer reasonable protection against accident hazards, poisons and dusts; adequate lighting, ventilation and sanitary facilities; care of industrial injuries; and routine medical examination of workers exposed to harmful dusts and to poisonous substances.

These are matters of common justice, as between man and man.

Second, the employer has a clear right (though not a moral responsibility) to provide any further health services which will promote efficiency in industrial production. Under this heading come such items as: physical examination of employees not exposed to special industrial hazards; diagnosis and treatment of non-industrial accidents and illnesses; special physiological and psychological services for the adjustment of the worker to his task; health education and advice as to health habits; provision of luncheon facilities and of opportunities for physical exercise and recreation. The National Industrial Conference Board, in the report cited above, states the argument for medical service from this standpoint of efficiency as follows:

There are two vital, coöperating factors in modern industry, the machine and the man who tends it. If ill health of the worker, causing labor turnover or absenteeism, stops the machine, there is a loss in output. In like manner, if the machine fails to run to its full capacity during working hours because the worker is listless or inattentive, there is loss in productive efficiency. One of the principal reasons for failure of the worker to do what he is capable of doing is an impaired physical condition. He may have a cold or other minor ailment, perhaps the beginning of a more serious illness, or he may have returned to work after an illness before he had gained his full strength. For one cause or another he has an impaired vitality which lowers his efficiency. When the services of a medical department are freely sought and freely given there is a continuous conservation of the health of the employees which keeps their efficiency at normal levels and enhances the value of their services to their employers.

The same report cites a particular instance in which absenteeism due to illness and accidents was reduced from 4 per cent of all working time to 1.3 per cent by health supervision. The cost of the medical service provided was \$6,398. The saving involved in workmen's compensation and group life

insurance premiums was estimated at \$2,848 and the saving to the company by reduced absenteeism at \$5,370—a total of \$8,218.

These two motives, then—justice and efficiency—are the sound bases of industrial health and welfare work. Anything which can be justified on either of these grounds is wise and reasonable. Anything which cannot be shown to contribute to one or the other of these ends is of doubtful value as an industrial activity. For industry which embarks on philanthropy (except in times of temporary and peculiar economic stress like the present one) lays itself open to the obvious criticism that if there are available such large profits as to justify philanthropy it would be sounder to turn such profits into increased wages or lowered costs and permit the employee or the purchaser to benefit himself in his own way.

In the present discussion we are concerned chiefly with those measures which extend beyond obvious moral obligation; and the first of these is the provision of health examinations for the general working staff. This practice has grown rapidly in recent years. The National Industrial Conference Board report states that of 1,818 companies covered in its 1930 survey, 53 per cent were making initial physical examinations of employees and 20 per cent subsequent periodic examinations. Miss Elizabeth Dublin in a more recent study made for the National Tuberculosis Association (courteously communicated to the writer in manuscript) has covered 6,012 plants employing 4,402,280 persons and reports that 5,542 of these plants with 4,105,171 employees had examinations before employment while 3,254 plants with 3,134,740 employees had subsequent periodic examinations for at least some of their employees. These figures are most surprising and encouraging.

The advantage of the physical ex-

amination, both to the employer and the employee, is very great. Its primary objective—even in the examination before employment—should not be rejection of the subnormal worker. The Conference Board of Physicians in Industry has laid down the principle that the applicant should be rejected only if his disability is such as to make his employment a menace to himself, to fellow employees or others, or to property. Of 221 plants reporting to the N.I.C.B. in 1930, 38 rejected more than 10 per cent of applicants as a result of the health examination, which indicates the application of an unduly severe standard. In general, nevertheless, it appears wholly reasonable that a company which may be called on to pay compensation should have a record of the physical condition of its workers prior to employment, and the benefit to the employee himself in the detection of correctible defects and in selection of a safe line of employment is inestimable.

The second field in which medical service in industry has broadened out has been in the diagnosis and treatment of non-compensable injuries and illnesses. Here, as in the case of the physical examination of workers engaged on tasks free from specific industrial hazards, there is no moral obligation involved. The reason for such developments is that minor illnesses form the major cause of industrial absenteeism. Experience has shown that prompt and competent medical care will materially reduce such temporary disability; and also that prompt and competent medical care is not generally available for the factory worker on terms and under conditions which actually lead to its utilization. Hence, many industries provide general diagnostic service for their employees, render first aid treatment in emergencies, and give assistance and counsel to the worker who requires more prolonged care.

These two types of activity, the health examination and the diagnosis and emergency treatment of illnesses of a non-industrial nature, represent fairly common extensions of industrial health service into the domain of general medicine. In certain instances, the process has gone much further; and it is these more extensive developments which I have indicated by the title "Industry in Medicine" and which I propose briefly to review.

If it be granted that maximum efficiency in industry depends on a working force which enjoys a maximum degree of physical and mental health, it is clear that the employer is vitally concerned with the general medical care available for his employees. If diagnostic service and first aid provided by the plant and other medical service provided by existing facilities of private medical practice and public clinic service are adequate, well and good. If such facilities are not meeting the situation, however, the employer may very properly consider whether a further extension of industrial health service will not bring returns commensurate with the cost involved.

According to Pierce Williams,² about 540,000 gainfully employed persons in mining and lumbering companies in 21 states were eligible in 1930 for medical care on such an organized basis. In consideration of a fixed periodic deduction from wages these employees are entitled to medical treatment for conditions not covered by workmen's compensation, the payment being sometimes voluntary and sometimes a condition of employment. These industries, it is obvious, are usually carried on in isolated regions where medical care could not be obtained unless it were furnished by the industry itself. Similar services are provided for about one-third of all the Class I railroads of the United States by memberships in employee hospital associations.

Finally, we must recognize that the industrial employee is generally not an isolated unit but a member of a family. If there is uncared for illness at home his worry and distress may gravely impair his efficiency. Where the local medical facilities are inadequate, may it not, therefore, be justifiable for industry to provide medical care for the family as well as for the worker himself? In a surprisingly large number of instances, this question too has been answered in the affirmative.

The Committee on the Costs of Medical Care has made several illuminating studies of enterprises of this kind. The Endicott-Johnson Company of Binghamton, N. Y., for example, provides very complete medical care for all its employees and their families.³ The service covers all ordinary types of medical care for ambulant and bed cases, including physical therapy, X-ray therapy, heliotherapy, and the services of a psychologist for patients not overtly psychotic. It covers dentistry so far as simple repair, extractions, and hygiene are concerned. It covers nursing in home as well as in hospital. It provides drugs and medicines free; but not orthopedic supplies and eyeglasses except to those reported as unable to pay for them.

The organization maintains three medical centers each including hospital service, a first aid station and clinic, and several travelling clinics. The staff in 1928 included 28 physicians, 4 dentists, 5 dental hygienists, 2 physical therapists, 67 trained nurses, 4 bacteriologists, 4 pharmacists, 17 technicians, and 16 clerks and office assistants. The organization in addition calls extensively on outside facilities, having spent \$250,000 in 1928 for care of patients in community hospitals and \$40,000 for outside specialist and consultant service.

There were 15,230 workers employed by this company during the year 1928

with 25,891 dependents (according to Carpenter's estimate), a total of 41,121 persons eligible for service. Carpenter concluded from a special sampling study that 77 per cent of these persons used the company service only, and an additional 17 per cent used it in part. The total cost of the medical organization was \$898,874 or \$25.49 per year per individual in those families which actually used the service.

The quality of the medical service rendered (as reported upon by highly qualified experts in medicine and surgery) was equal to or better than that provided in similar areas by private physicians; and free choice of physician within the staff and the general flexibility of the system secured a high degree of sound personal relationship between physician and patient.

As pointed out, industrial medical services of this type have most often been provided in remote areas where no private practitioners were available. Even in more urban communities, however, there are distinct advantages in such a program. The first and foremost of these advantages is that under such an organized program medical advice will be far more generally utilized for health examinations and for the early treatment of incipient disease than would be the case if the individual were left to seek and to pay for medical services on his own initiative. Since prevention and early recognition of incipient disorders form the keystones of modern medicine it is difficult to exaggerate the importance of this factor. The second major argument for an organized medical program serving a group of industrial employees is of course the economy of overhead charges and of the time of professional personnel which is involved.

These values of an industrial medical service are excellently illustrated by another of the studies of the Committee on the Costs of Medical Care dealing

with the Homestake Mining Company.⁴ This is a corporation mining gold in the Black Hills of South Dakota with headquarters in the town of Lead. It employed in 1930 an average of 1,855 persons and provided medical care without charge for all these employees and their dependents—a total of 5,332 persons. The service included all forms of medical and hospital care but not dental care and not home nursing. Medicines were provided free but eyeglasses only at cost. The company maintained a 26-bed hospital with a well equipped dispensary including laboratories, X-ray and physiotherapy rooms. The staff consisted of 5 full-time physicians, 6 registered nurses, and a dispensary nurse. Employees had free choice among the 5 physicians and relationship with patients was close and intimate. The total cost of the medical department in 1930 was \$79,326, or \$14.88 per person served.

From the standpoint of completeness, Reed compares the volume of service rendered with that actually received by groups of the general population of the United States at comparable economic levels (as revealed by other studies of the Committee on the Costs of Medical Care). He finds that the amount of hospital care for the Homestake group (excluding industrial accidents) is almost exactly the same as that for the general population (0.6 day per person per year); while the number of medical home calls (2.1 per person per year) is about twice that for the general population, and the number of office and clinic calls (8.7 per person per year) is more than 6 times that for the general population.

The values from the standpoint of economy are equally clear. Reed analyzed the Homestake records with great care as to the exact number of services of each kind which were rendered and estimated the cost of such services at the prevailing rates in force

in districts adjacent to Lead. He found that the services which actually cost \$79,326 would have cost \$175,378 if obtained under ordinary conditions. Yet the medical staff of the company receive salaries well above the average for similar areas.

There are obviously certain dangers which inhere in any such program which involves the conduct of medical practice under lay control. These dangers fully justify the opposition of the American Medical Association to any form of contract practice which involves unfair competition. It seems clear, however, that "unfair competition" cannot be held to result from superior efficiency and economy of organization since the basis of medical ethics is ultimately the welfare of the patient. "Unfair competition" exists when either (a) the service rendered to the patients is below standard, or (b) when the physicians employed are exploited by under-pay or overwork (which in the long run must of course operate to the detriment of the patients themselves). These dangers must be constantly guarded against in industrial medical services. They do not appear to be manifest in either the Endicott-Johnson or the Homestake program.

In both the instances cited, the entire cost of the medical service was borne by the industry concerned. In other instances organized medical programs have been developed under the auspices of employee groups. Examples of this type are to be found in the operation of a hospital with a salaried medical staff by a branch of the United Mine Workers of America at West Frankfort, Ill., and in the provision of medical care through part-time salaried physicians by the New York Letter Carriers' Association. According to Pierce Williams in the report cited:

In by far the greater number of industrial medical services, the provision of care is financed jointly by the company management

and by the employees. Such arrangements usually develop from contracts which the companies draw up with local medical practitioners and hospitals, or from the organization of a medical department under the company's direction. The employees contribute through payroll deductions.

Williams cites the services in the mining and lumbering industries and in railroading as examples of this type of organization, which seems a highly promising one. The psychological relationship between physician and patient and the attitude of the employee toward the service as a whole are likely to be sounder and more fruitful if the employee realizes that he is contributing toward the support of the program.

As illustrating how a medical organization may be developed through a group of small industries acting jointly for the service not only of their own employees but of other members of the community, we may consider one final example—that of Roanoke Rapids, N. C. This is the third of the special industrial studies of the Committee on the Costs of Medical Care.⁵

The program at Roanoke Rapids began with the employment of physicians by the local cotton mills. To meet obvious local needs these physicians on their own initiative established a hospital which was later purchased and enlarged by the mill corporations. At this time (in 1924) the employees of the mills, with only 4 negative votes among 2,500 employees, approved a payroll deduction of \$.25 a week to pay for hospital care. The program therefore represents a rather unusual coöperation between employers, employees, and medical staff in which all three have played an active part.

The organization in 1930 was as follows—5 physicians and 3 visiting nurses were employed by 4 industrial establishments to care for their employees, and the employees of these 4 companies and of a fifth company contributed \$.25 a week for hospital costs. Al-

though the physicians and nurses were separately and independently employed by the various firms, they operated as a group, with free choice for the entire population served and with some degree of specialization in surgery, pediatrics, and internal medicine. Home, dispensary and hospital care and home and hospital nursing are all provided to the group of mill employees and their dependents and to local groups of teachers and nurses, a total of 4,919 persons. Dentistry and drugs are not provided.

The rest of the population (5,693 persons) is cared for by the same medical staff (and by the one additional physician in the community, a specialist in eye, ear, nose and throat work) on a fee basis since the salaried physicians are permitted to do outside practice in their spare time.

This arrangement made it possible to compare services and costs for two approximately equal population groups in the same community, one served on an organized and the other on an unorganized basis. The economic status of the two groups was approximately equal (\$24.50 per week income per family for the mill group as compared with \$27.16 for the non-mill group).

The mill group paid \$17.44 per capita during the year for medical services, the non-mill group, \$10.34. About one-third of the \$17.44 came from the employees directly in monthly check-off plus additional costs paid individually, the other two-thirds from the companies. This, of course, illustrates the fact that an organized contributory program, plus a subsidy from the employer, increases the total amount of money available for the costs of medical care. For this additional 70 per cent of expenditure, moreover, the mill group actually received over 500 per cent more days of hospital care, 350 per cent more clinic visits and 240 per cent more home calls. The actual figures (for a

typical group intensively studied): 3.2 patient days a year for hospital care in the mill group as against 0.5 day for the non-mill group; 1.8 dispensary visits per year for the mill group as against 0.4 for the non-mill group; 2.4 home calls a year for the mill group as against 0.7 for the non-mill group.

It seems clear to the writer that two basic principles must govern the development of medical service in the United States if the potential resources of modern medicine are to be made really available for all the people under conditions of maximum effectiveness.

In the first place the studies of the Committee on the Costs of Medical Care have demonstrated the great advantages of organization of the professional personnel and equipment which renders the medical service. Such organization may be effected by the profession itself, by an industry or some other agency representing the patient, or by the coöperation of both; but, if soundly and wisely planned it benefits both profession and patient. The patient receives better service from an organized than an unorganized service, for a given individual physician will be both psychologically stimulated and materially assisted by working in intimate relationship with a group of his peers, and the patient receives a given service at substantially lower cost on account of the saving of overhead and of professional time inherent in organization. Similarly, the physician gains from group practice better conditions for work and larger and more assured income.

In the second place, it is equally clear that the consumers of medical service should be organized so as to facilitate the payment for such service. The average costs of medical care are too low rather than too high. What causes our difficulties is the fact that illness is an emergency. While many families in a given year pay little or

nothing, one family out of a hundred will be crippled by costs equivalent to a quarter or a half of its annual income. It is quite obvious that here, as with other emergencies of life, the rational answer is to apply the principle of insurance. Whether the funds come from a group of individual families, from their employers, from the state, or from two or all of these three sources, the payment into a common fund of a certain sum for each family each year is the essential element in the scheme. Such an arrangement wipes out the burdens of the care of emergency illness by spreading them over a group of families and a period of time. It makes easily available considerably larger total sums for medical care than could otherwise be secured. Finally, and perhaps most important of all, it makes possible a true preventive medicine, based on the health examination and the prompt treatment of incipient disease, such as can never be attained when the consultation of a physician calls for an immediate corresponding financial obligation.

There are many and various ways in which such organization for the delivery of medical service and such organization for the payment for medical service can be attained. On the professional side, it would seem ideally desirable that the organization should take place under professional auspices, with such safeguards for the public interests as are furnished for example by the Board of Trustees of a voluntary public hospital. I can visualize a time when such hospitals will attach to themselves the great majority of physicians in their respective areas and will provide complete hospital, dispensary and domiciliary care on a fixed annual fee basis. If medical agencies fail to take the initiative, however, lay agencies must do so; and industry will, in many communities, be in position to do what has been done at Bing-

hamton, Lead, and Roanoke Rapids.

On the payment side, the one logically complete answer to the problem is that given by compulsory state sickness insurance. This is the answer which has been given in practically all European countries; and it may prove to be the ultimate solution in the United States. The program has, however, shown serious defects even in Europe and these defects might perhaps be exaggerated in the political atmosphere which prevails on this side of the Atlantic. Here, as in many other fields of social endeavor, there is at least a possibility that industry—actuated by a new sense of social responsibility—can attain some of the ends sought by state action in Europe with results more in keeping with our national psychology. The extent to which American industry can evolve such a sense of social responsibility during the next 20 years will determine the issue.

“Medicine in Industry” has come to stay. It will always be essential that the employer should safeguard his workers against the specific hazards inherent in their employment. How far “Industry in Medicine” may develop, only time will show. It will, I think, come to be recognized that an organized program of medical services paid for on a periodic contributory basis is an essential of sound community life and therefore of industrial life which forms the basis of community life. Such a program will ultimately be carried out on a basis of state action if the need is not first met in some other way. I can see no other way for industrial communities than the organization of the payment side of the problem by the industries themselves—either contracting for organized medical service with hospitals, group clinics or other professional agencies or providing through industrial initiative the service as well as the system of payment. It will be well for the far-sighted industrialist to study

this problem with care, particularly if he is not anxious for the extension of governmental agencies into new fields of activity.

Scholastic Standing and Mouth Condition

IN 1912, Dr. Fones, of Bridgeport, Conn., found that 40 per cent of the children in that city showed retardation in their school work. He began the practice of dental hygiene on them, and 4 years later, the number of deficient children was reduced to 20 per cent.

In Atlanta, Ga., Dr. Sutton found that after the mouths of school children were put into healthy condition, the percentage of failures dropped from 22 to 8 per cent.

Recently, 164 junior high school boys in Minneapolis averaging 14. years of age were subjected to a similar experiment, 56 being among the best pupils of the school, 59 among the worst, and a third group of 49 were used as controls. The dental examinations were made with no knowledge of the

scholastic standings of the boys. A careful record was kept and the mouth conditions graded as excellent, good, fair, or poor. Of 7 boys who had excellent teeth, 6 were in the group of excellent students, and only 1 poor, and of those having poor mouths, 5 were poor students, 3 were in the control group, and 1 was excellent. Of the excellent students, 70 per cent had mouths which were either excellent or good, while of the poor students, only 51 per cent were in these two classes. The study is being continued on larger groups and attempts being made to correlate the mouth conditions of the children with the occupational status of fathers.—Joseph T. Cohen, D.D.S. Scholastic Standing and Mouth Condition, *Mouth Health Quart.*, Jan., 1933.

Suggested Method of Computing and Standardizing the Maternal Mortality Rate*

ROBERT J. LOWRIE, M.D.

Attending Obstetrician, St. Vincent's Hospital, New York, N. Y.

SINCE the publication of my original paper¹ on this subject I have had, from different parts of the world, several letters containing criticisms and suggestions regarding the proposed method of computing and standardizing the maternal death rate. As the method suggested necessarily involves some of the principles of the present method, a good share of the criticisms aimed at me also strike at the method now in vogue of arriving at the maternal death rate. My paper, then, has evidently served a twofold purpose.

The present work is the result of an attempt to rewrite the original article in simpler form, using as a guide the material found in those letters which my correspondents have kindly forwarded to me.

In the United States for the year 1928 the maternal death rate was 69 per 10,000 live births. For the same year in the Netherlands the rate was 34 per 10,000 live births. Does this mean that the pregnant woman in the United States actually runs double the risk of dying in childbirth of her sister in the Netherlands? Or might the difference in the two rates be due, in some

measure, to variation in methods of computation?

Of late, considerable attention has been directed toward certain fallacies which may arise in the comparison of maternal death rates. The League of Nations has given several reasons why comparison of International Vital Statistics may lead to erroneous conclusions. The publications of the U. S. Bureau of the Census also caution the reader in this regard.

Hospitals, maternal welfare or visiting nurse organizations, etc., sometimes quote their maternal death rates and then commit the unpardonable error of comparing these "low" rates with the "high" rate of the country as a whole.

The death rate of the maternity hospital or organization is a *selective* and necessarily lower rate than that of the community or country of which it is a mere sample. There are two chief reasons for this: (1) the difficulty, especially in a large metropolitan center, of following to the end of 1 month after birth *all* women registered for childbirth; (2) the maternity institution being primarily concerned with birth of children has on its records a relatively small proportion of cases such as abortion, miscarriage, ectopic. However, the deaths from these, as well as the deaths of women not accounted for 1 month after giving birth, appear on the roster of the Board of Health.

* Read before the Child Hygiene Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932.

Yet from surveys such as these has emanated the widely disseminated assertion that in the United States 2 of every 3 maternal deaths are unnecessary.

Physicians actually in attendance on confinement cases terminating fatally often find it difficult to state on the certificate whether death was due to childbirth or to some complicating condition such as heart disease, tuberculosis, etc. His opinion as to the cause of death is final only if it agrees with the vital statistician's interpretation of the classification in the *International List of Causes of Death*. It is readily seen that the maternal death rate may vary with precision of application of the rules for allocation of causes of death, and this quite independent of number of deaths. In spite of this possible obvious disparity, the maternal death rate is computed to within 0.1 per cent.

The primary object of computing a death rate is to compare it with that of some other community or country. It is important, therefore, that if death rates of different areas are to be compared, first, all deaths must be included, and second, there must be some standard method of computation. The crude, general and true death rate is the result of computing the relation between the *exposure group*, or number of persons alive at the beginning of an interval of time, and the number in that exposure group who died during the same interval.

In case of the maternal death rate the method of computation is somewhat different. If in a given area in a given year, 668 women died of causes directly assignable to childbirth, and if during that year there were 121,462 babies registered as born alive, then the maternal death rate is 55 per 10,000 live births, as given by

$$\frac{668}{121,462} \times 10,000 = 55 \dots \dots (1)$$

Because of the very incomplete registration of pregnancies which issue in the form of abortion, miscarriage, and ectopic gestation, there is no accurate record of the number of women in whom pregnancy terminated in less than 28 weeks. Since the number of live births from pregnancies under 28 weeks is very small, the exposure group in the definition of maternal death rate, 121,462 in equation (1) above, refers practically only to the last 12 weeks of pregnancy. The number of deaths, 668, refers, however, to the whole 40 weeks of pregnancy. The denominator of (1) is short the number of women whose pregnancy ended under 28 weeks. The effect of this is to give a relatively high value for the maternal death rate.

As the denominator, 121,462, of the fraction for getting the maternal death rate refers only to "live" births, it is readily seen that the rate would rise in proportion to deficiency in birth registration. The same thing might happen where the proportion of live births—of *all* births—was relatively low.

It is seen then, that the maternal death rate as defined in terms of registered live births, varies with the rigidity of application of the rules for allocation of causes of death; is overstated by its own definition; increases with deficiency of birth registration, and with the number of maternal deaths which occur before birth of child; very probably increases where the proportion of live births in all births is relatively low.

It is quite natural then that we should seek a method of measuring the maternal death rate which would be free of the variables mentioned above, which would conform to the definition of the crude or true death rate, and which could be used to make reliable comparisons, national or international.

Registration of births of gestation 28 or more weeks permits of a method

(q.v.) of computing the corresponding exposure group of women, which when related to the deaths in this *same* group gives the death rate of women in this span of pregnancy. But there still remains to be considered those women whose pregnancies terminate by abortion, miscarriage, or ectopic. The incomplete registration of these does not allow of calculation of the exposure group and hence of a true death rate. These deaths might be related to the number of non-childbearing females in the same age class, or they could be stated as a percentage of the total deaths for all periods of gestation. Employment of either of these two methods is merely making the best of the situation.

A woman pregnant 28 or more weeks is said to have a *viable pregnancy*. This class of women I have designated the *childbearing group*, or the exposure group.

The number of deaths in women in the childbearing group is, of course, the number of death certificates in women pregnant 28 or more weeks, on which certificates pregnancy or childbirth is given as *either the primary or contributing cause of death*. Pregnancy advanced to the period of viability, or even to the 5th or 6th month, is not likely to escape mention by the medical attendant. When necessary, further information as to period of gestation and whether death occurred before or after delivery, can be obtained by a supplementary communication to the physician. Generally speaking, this information is as available as any other data on the death certificate.

As practically all deaths related to pregnancy or childbirth have occurred by the end of 1 month after birth, we shall consider all deaths in childbearing women which take place during the pregnancy or within 1 month after birth.

The exposure or childbearing group is obtained from birth registration data and is the number of women in whom pregnancy terminated by live birth or stillbirth during or after the 28th week of uterogestation. Referring to these viable pregnancies, the number of women in the exposure group would be found by adding the live births to the stillbirths, deducting 1 and 2 for twins and triplets, and adding the number of women who died before giving birth.

Unfortunately, bureaus of vital statistics do not usually make a separate tabulation of stillbirths of gestation 28 or more weeks. Also, the number of multiple (twin or triplet) births listed may include cases of gestation under 28 weeks. On the other hand, the registered live births is a much more reliable figure and it can, when necessary, be corrected for any deficiency in birth registration. Furthermore a "live birth" practically always implies gestation of 28 or more weeks. Therefore, in case of live births, classification of these in terms of gestation is not necessary in arriving at the exposure group.

If bureaus of vital statistics would furnish separate tabulations for multiple births and stillbirths of gestation period 28 or more weeks, then the number of women in the exposure or childbearing group is very accurately and readily obtained. It should be remembered that most women bearing children can be just as accurate about the time of expected confinement as they are in regard to giving their age.

There is a second, and I think fairly reliable method of calculating the exposure group. It has no direct relation to plural births or to stillbirths. An institution such as a maternity hospital or maternity service can have, and usually has, complete record of *all* births as well as the period of uterogestation of each woman giving birth. If we deduct the number of women

whose pregnancies terminated under 28 weeks and then relate this remainder to the number of number of live births we can get a very useful ratio.

In Table I is shown a representative and aggregate sample of consecutive cases from 5 maternity services in greater New York, in the year 1930. The ratio of childbearing women to live births multiplied by 1,000 (column 3) is what I have chosen to call the "converting ratio."

The result for the converting ratio obtained in column 3 of Table I allows us to say, for the representative sample, that for every 1,000 babies born alive there were 1,110 childbearing women. Assuming, as we have done, that our sample is a representative cross-section of the whole city, then the number of women bearing children in New York City is found by multiplying the number of live births, 74,233, by the value of the converting ratio, 1,010/1,000, giving 74,975 (column 5).

Generally speaking, the proportion of live births in home confinements is probably comparable to that of the institution. It is true that the difficult cases are more liable to gravitate to the hospital, but it is also true that the hospital has more facilities for conserving life. As may be seen later, a fairly wide margin of error in the converting ratio gives rise to a relatively small deviation in the computed death rate.

In Table II the number of women bearing children, 74,975, when added to the number of women who died before giving birth, gives us in column 3 the number of women in the exposure or childbearing group, viz., 75,009. When the number of deaths from all causes in women in childbearing or exposure group, 246, is divided by the number of women in the group, 75,009, we obtain as is shown by column 5 of Table II and by the equation

$$\frac{246}{75,009} \times 1000 = 3.28 \dots \dots (2)$$

TABLE I
THE NUMBER OF WOMEN BEARING CHILDREN, OBTAINED FROM REGISTERED LIVE BIRTHS
BY THE METHOD OF THE CONVERTING RATIO

TABLE II

DEATH RATE IN CHILDBEARING WOMEN IN AGE CLASS 20-29 FOR NEW YORK CITY IN YEAR 1930

| (1) | (2) | (3) | (4) | (5) |
|------------------------|------------------------------|-----------------------------|---|--|
| Women bearing children | Deaths before birth of child | Women in childbearing group | Deaths from all causes in childbearing women during pregnancy or within 1 month after birth | Death rate in childbearing group $\frac{\text{Column 4}}{\text{Column 3}} \times 1,000$ |
| 74,975 | 34* | 75,009 | 246† | 3.28 per 1,000 |

* There were 68 women in all age groups who died before giving birth. As about half the births occur in the age class 20-29, I have assumed likewise that about half the deaths, viz, 34, also took place at these ages.

† In the age class 20-29 there were 319 deaths in women at any period of gestation. Referring to all ages, of the total of 667 deaths, 515 or about 78 per cent were in women pregnant 28 or more weeks. On the assumption that the proportion 78 per cent holds good, approximately, for the separate age groups, 246 is found, by taking 78 per cent of 319. It will be seen then that this assumption will have the effect of slightly under- or over-stating the death rate in the separate age groups. In this series I have been given to understand that practically all deaths in women pregnant 28 or more weeks are listed as of maternal origin.

the death rate of 3.28 per 1,000 for women in the childbearing group.

In equation (2) we have an expression which conforms to the definition of the crude or general death rate. It is therefore the true death rate from all causes of childbearing women in age class 20-29. It is seen that the true death rate, so arrived at, involves no element of correction or personal equation. It depends only on standard data—age of mother, status in pregnancy, and relation of death thereto—all of which can be obtained by birth and death certification in any locality or in any country.

In making a comparative study of maternal death rates it is this general death rate in childbearing women to which we should direct our attention, rather than the corrected rate given in terms of live births which, as we have seen, can by its own definition, vary within wide limits.

In my original paper I did not compute rates for the separate age groups. For this I have been criticised and, I

presume, rightly. It may be noticed, however, that this criticism has not been aimed at the present method, giving the rate in terms of maternal deaths per 1,000 live births.

The crude and general death rate for childbearing women in the age class 30-34 in New York City, 1930, I have computed in the same way and find it to be 4.69 per 1,000.

We have seen, for instance in the age class 20-29, that the 3.28 per 1,000 of equation (2) includes all deaths. If we use round numbers and regard the rate as 328 per 100,000 we may ask in how many of the 328 women death was caused by some complicating ailment such as heart disease or tuberculosis. How many of them would have died even if not pregnant? Or, what is the death rate in puerperal women from causes other than childbirth—the so-called normal death rate? If such a rate can be obtained and then subtracted from the general death rate in childbearing women the remainder is the death rate in women who died solely

TABLE III

New York City

Age Class 20-29

| Childbearing Women | | Married, Non-childbearing Women | |
|---|--------------------------|---|--------------------------|
| Number | (1) (a) 75,009 | Total married women | (2) (a) 371,992 |
| Deaths during pregnancy or within one month after birth | (b) 246 | Married non-childbearing women 2 (a) less 1 (a) | (b) 296,983 |
| | | Deaths in married non-childbearing women Census figure less 1 (b) | (c) 1,041 |
| Death rate (Applies for only 16 weeks of year) | (c) 3.28 per 1,000 | Death rate in married non-childbearing women (Applies for whole year) | (d) 3.50 per 1,000 |

because of pregnancy and childbirth—the death rate *per se* due to pregnancy and childbirth.

In attempting to get a value for the normal death rate we should examine the death rate in a group of women identical with childbearing women except as to pregnancy and childbirth. We might then regard, for the particular year and age class, the death rate in married non-childbearing women. This data can be obtained from bureaus of vital statistics and from the census figures.

In Table III is shown the death rate in childbearing women and the rate in married non-childbearing women for the age class 20-29 in a given year. As may be found from actual computation, a wide margin of error incident to estimating the population for an intercensus year involves a relatively small deviation in the computed death rate.

If the death rate in married non-childbearing women is to be compared with that of the childbearing group we must multiply by 16/52. Then, by subtracting the two rates and placing them in equation form we have, for age class 20-29,

$$\frac{3.28}{1,000} - \frac{16}{52} \times \frac{3.50}{1,000} = \frac{2.20}{1,000} \dots (3)$$

$$\frac{328}{100,000} - \frac{108}{100,000} = \frac{220}{100,000} \dots (4)$$

The interpretation of equation (4) may be given as follows, and is subject to the truthfulness of the assumptions used in obtaining the data for Tables I, II and III: In New York City in the year 1930, referring to age class 20-29, of every 100,000 women who entered the 28th week of pregnancy, 328 died during pregnancy or within 1 month after birth. In that 328 there were 108 whose primary cause of death was not pregnancy or childbirth, but rather some associated condition such as heart disease or tuberculosis; and of the 328, the remainder 220, died primarily because of pregnancy or childbirth. The rate, 220 per 100,000 childbearing women, is the death due to pregnancy and childbirth, *per se*.

For the age class 30-34 in the year 1930 in New York City the death rate *per se* was computed in the same way and found to be 352 per 100,000.

When this rate is compared with the 220 per 100,000 for age group 20-29 it is readily seen that the rate *per se* increases with advance of age, and this quite apart from the increase in the general death rate due to age.

In the original paper the deductive factor, represented as 108 per 100,000 in equation (4) in the present work, included all women who did not bear children during the year. One or two of my critics pointed out that inasmuch as the death rate in those physically or mentally unfit for marriage would be relatively high, the deductive factor would be correspondingly raised, and hence the death rate *per se* would be proportionately understated. With this in mind, I have made up Table IV.

On comparing the two values of the deductive factor for the same age class, in Table IV, does it seem to make very much difference whether or not the deductive factor takes into account marital status? Of course, Table IV represents only 1 year in New York City.

It will be seen that equation (4) is true only if the normal death rate in childbearing women (the rate of death from causes other than puerperal) equals the value of the deductive factor. The right to assume this has been questioned. James B. Russell and I are at present gathering some data pertinent to this matter and we are testing out a modified* form of equation (4).

* Referring to women age x , let $cQ'x$ be the death rate in childbearing women due to pregnancy and childbirth, cQx the normal death rate in childbearing women, $ncQx$ the death rate in women not in the childbearing group; also let $cQx/\text{---}ncQx=K$, then the death rate due to pregnancy and childbirth *per se* for the last 12 weeks of pregnancy and first 4 weeks after birth is:

$$cQ'x = (cQ'x + cQx) - K - ncQx \dots\dots\dots (5)$$

If the normal death rate equals the deductive factor, then $K=1$ and the equation becomes

$$cQ'x = (cQ'x + cQx) - \text{---} ncQx \text{ which is the general form of equation (4) above.}$$

We observe from Table IV, age class 20-29, that the rate of death *per se* is about two-thirds the crude death rate. If we were to compute the maternal death rates in terms of live births, we should also find approximately the same relation. In the age class 30-34 (line 2 of Table IV), the death rate *per se* is about one-quarter less than the crude death rate. There seems to be no reason to suppose that this excess of a quarter or a third would not also be true for deaths in women pregnant less than 28 weeks. The proposed method of computation then, may serve as a check on the present method. In view of the fact that New York City affords a real representative cross-section of a cosmopolitan population, and assuming that 1930 is very probably not different from any other year, may we hazard the guess that the maternal death rate as computed by the present method, is a quarter to a third overstated?

SUMMARY

It is thought that the present method of computing the maternal mortality rate, as the relation between maternal deaths and registered live births, is subject to several sources of error:

1. It varies with the precision of application of the rules for the allocation of causes of death.
2. It is overstated by its own definition.
3. It increases in proportion with deficiency of birth registration and with the number of maternal deaths occurring before birth of child.
4. It very probably increases when the proportion of live births—of the total of all births—is relatively low.

Because of the errors incident to computation of maternal death rates by the present method, the comparison of maternal mortality rates in different areas or countries may often lead to unwarranted conclusions.

Sweeping generalizations from rates in small samples usually lead to mis-

TABLE IV

THE DEDUCTIVE FACTOR IN THE MATERNAL MORTALITY RATE, PER SE, NEW YORK CITY 1930

| Components of the deductive factor | Age class | True death rate per 1,000 | Deductive factor per 1,000 | Mortality rate per se (per 1,000) |
|---|-----------|---------------------------|----------------------------|-----------------------------------|
| Married women not bearing children | 20-29 | 3.28 | 1.08 | 2.20 (1) |
| | 30-34 | 4.69 | 1.17 | 3.52 (2) |
| Married, single, widowed or divorced women not bearing children | 20-29 | 3.28 | 0.98 | 2.30 (3) |
| | 30-34 | 4.69 | 1.18 | 3.51 (4) |

interpretation. It has been pointed out that the death rate of a country, state, or large center is the representative and nonselective rate while that of the maternity organization—hospital, visiting nurse service, etc., is necessarily a selective rate and one which does not represent conditions in general.

A low maternal death rate attainable in an institution in a large center does not imply that the rate for the country at large could be reduced to the same level.

Bureaus of vital statistics usually do not have record of the number of women giving birth. If these bureaus would make a separate tabulation of stillbirths and multiple births of gestation 28 or more weeks, the number of women pregnant 28 or more weeks (childbearing group) would be found by adding these live births and stillbirths to the number of childbearing women who died before delivery and then deducting one and two respectively for each set of twins or triplets. If these tabulations are not available, then the number of childbearing women in a given area may be obtained from the number of live births in that area by the method of the converting ratio as shown in Tables I and II.

The exposure or childbearing group of women, however gotten, when related to *all* deaths in that group, gives the crude, true and uncorrected death rate from all causes in childbearing women.

It is this true and uncorrected death rate which should receive first consideration when national or international comparisons are made.

The death rate due to pregnancy and childbirth *per se* is calculated by deducting from the crude death rate the so-called normal death rate or death rate in childbearing women from causes other than puerperal. Generally speaking, the normal death rate in a country for a given age class should parallel the general or crude death rate (from all causes) in the same age class. It should be remembered that the maternal death rate in a certain country may be high partly because that country has a high general death rate in women of comparable age. It is in such a circumstance that the mortality rate due to pregnancy and childbirth *per se* has an important application.

In closing, let me state that the main object of this paper is the presentation of methods rather than the exhibition of death rates arising therefrom. It is hoped, at least, that the suggested scheme will stimulate a few individuals to further research. The author will gladly assist any workers who may have difficulty in applying actual data to the tables or equations for arriving at rates.

Present Status of Handling Water Samples*

Comparison of Bacteriological Analyses Under Varying Temperature and Holding Con- ditions With Special Reference to the Direct Method

ELFREDA L. CALDWELL AND LELAND W. PARR, PH.D.

*Director and Chief Bacteriologist, Field Research Laboratory, Alabama State
Department of Health, Andalusia, Ala.†*

ACCORDING to *Standard Methods of Water Analysis* of the American Public Health Association¹ the time required between collection of a sample for bacteriological analysis and the beginning of the analysis should not exceed 6 hours for impure water nor 12 hours for relatively pure waters; and during the period of storage the temperature should be kept between 6° and 10° C.; and any deviation from these limits should be so stated in making reports.

To determine to what extent and for what reasons deviations from this standard exist a questionnaire to each state and insular official² responsible for the water analysis of his particular area requested information on the use of ice in transporting and storing samples and the time elapsing between sampling and analysis. Fifty replies were received, only 2 insular authorities failing to respond.

Analysis of the replies indicates that the use of ice in the storage and transportation of water samples intended for bacteriological analysis is a rapidly declining practice. Fourteen states have given up the use of ice entirely, of which 5 are southern subject to fairly long seasons of summer heat, though none from the extreme South, and another after experimentation reports its intention to do so shortly. Including this state, only 11 state and insular laboratories reported the examination of iced samples only; 25 laboratories analyze both iced and un-iced samples, though in 6 of these the practice is tantamount to examination of un-iced samples. One or more of the following conditions govern the procedure in the other 19 laboratories:

- a. Iced when collected by the Board of Health; otherwise un-iced
- b. Iced in hot weather
- c. Municipal samples iced, private samples un-iced.
- d. Iced when not examined promptly.

The reasons given for the increasing use of un-iced samples may be resolved into the following points:

- a. With modern transportation facilities, because of their size some of the smaller

* Read before the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

† Funds for the work of this laboratory are contributed by the International Health Division of the Rockefeller Foundation.

states and, through the establishment of branch laboratories, several of the larger states, feel that laboratory service has been brought within a few hours of all parts of the state.

b. Climatic conditions in some northern states preclude the need for ice.

c. Icing is expensive, often not practicable in remote areas, and frequently not carried out properly.

d. Un-iced mail samples have been found economical and practicable.

e. Many states do not ice if the analysis is carried out within 24 to 30 hours after sampling, since they consider icing necessary chiefly to safeguard the total counts on plates, which they omit except in certain technical controls.

No laboratory gave information as to the temperature of samples, iced or un-iced, at the time of analysis although several remarked that the use of ice had not been entirely satisfactory.

It is not improbable that the work of Berry³ has considerably influenced this tendency toward the use of un-iced samples. He concluded:

The number of Colon group bacteria in samples of ground water did not change materially in the first 48 hours after collection regardless of whether the samples were kept at ordinary temperatures or packed in ice. Samples shipped without ice-packing will, therefore, yield dependable results and may be safely utilized where ice-packing is impracticable.

Not all the 50 laboratories answering the questionnaire gave information as to time elapsing between sampling and analysis, and many of the replies are open to misinterpretation. Of those making definite statements we interpreted that:

13 states begin analysis within 24 hours after collection

15 states within 48 hours

6 analyze samples sometimes 3 or more days old.

It is unquestionably true that despite modern transportation facilities, a considerable number of water samples are more than 2 days enroute and a large

number are not examined within 24 hours.

In the study of possible contamination of water supplies from latrines bored or excavated into ground water, it was important that the recovery of the test organism should indicate the true character of the ground water being tested. To minimize uncertainties due to the shipment of water samples, we adopted the "direct" method as standard. Samples were inoculated into lactose broth (3, 10 c.c.; 2, 1 c.c.; and 2, 0.1 c.c. volumes) and plated in Endo (1 c.c.) on the field immediately after collection of the test samples and examinations were completed at the Field Research Laboratory. Because of the large volume of work involved it was not possible to incubate the cultures immediately on the field. The time interval between inoculations and placing cultures in the incubator ranged from 15 minutes to 5 hours with an approximate average of 3 hours. Frequently atmospheric temperatures approximated 37° C. or were sufficiently high for growth. In any case direct inoculations served to fix the test volumes in culture before changes in water samples could occur.

Methods Compared—In view of the varying practices summarized in Part I, it seemed worthwhile to compare our findings by the "direct" method with analyses of samples collected at the same time but examined after being held for varying periods under temperature conditions representative of these procedures. Samples were, therefore, collected from the same source at the same time and treated as follows:

Direct (D), as indicated above

Iced (I), ice-packed when collected and examined within a few hours

Un-iced (U), held at atmospheric temperatures and examined simultaneously with the iced

Express-Iced (EI), ice-packed when collected and held for 24 to 30 hours before examination

Express-Un-iced (EU), held at atmospheric temperatures and examined simultaneously with the express-iced

There were 672 duplicate samples examined direct and iced only, and 316 by all 5 methods. Though occasionally iced samples were held for 7.5 hours, by far the greater proportion were examined within 4 to 5 hours. When atmospheric temperatures were high and the holding period brief, the final temperatures of the iced samples did not fall to 10° C., occasionally registering 13° to 15° C. The majority recorded less than 10° C. As frequently happens in the shipment of samples to central laboratories, in very hot weather the ice melted in 24 to 30 hours. The final temperatures of express iced samples were, therefore, higher at times than 10° C., in cold weather recorded a low of 4.5° C., and averaged 17.1° C. for quintuplicate examinations. Un-iced samples fluctuated from 15° to 36.2° C. The temperature of the ground water, varied from 16.5° to 25.0° C., averaging 19.9° C.

Source of Samples—We had the advantage of a more exact knowledge of our sources than is generally possible. The greater proportion of samples derived from pipe wells in our experimental fields afforded waters of varying quality: (1) good water, (2) yielding *B. acrogenes* (soil) from infected pumps,⁴ and (3) receiving contamina-

tion or having been contaminated from experimental latrines. Group 4 includes a few samples from outside sources representative of water of poor quality contaminated from the surface and handling only—i.e., from shallow, unprotected dug and driven wells and surface waters.

Method of Bacteriological Examinations—In addition to *Standard Methods* for confirmed tests, the methyl red, indol and citrate tests were routinely employed to differentiate the colon-aerogenes group (hereinafter designated C-A) into 3 standard types—*B. coli*, *B. acrogenes* and Intermediates.⁵ In a very careful search for *B. coli*, streakings were made from 2 dilutions at the end both of 24 and 48 hours, if gas production warranted. In general a minimum of 4 to 8 colonies were picked according to gas production in varying dilutions. The presence of anaerobes of the *Cl. Welchii* type was confirmed. *Pseudomonas* complications were controlled by successive re-platings. In the examination of Endo pour plates, colonies were grouped into (a) "C-A reds" and (b) "Others"—tiny whites predominating among the latter. Since 1 c.c. was routinely employed to obtain an accurate picture of C-A reds, when other colonies exceeded 1,000 in number they were not further estimated but recorded as > 1,000.

For simplicity we shall compare our

TABULATION A

| Collections | #Samples | Method | Time in Hours | | Temp. Water °C. | | Maximum Air Temp. | |

findings in terms (1) of the recovery of the C-A group as a whole, and (2) of its component member, *B. coli*.

THE FINDINGS

Direct and Iced Only—Since it had not been demonstrated that the direct method was feasible or would offer any advantages over iced samples inoculated within a few hours and incubated immediately, 672 duplicate direct and iced samples were analyzed. The very low recovery of lactose fermenters (1.0 per cent) and absence of C-A reds on pour plate from 604 duplicate samples of good water indicated that direct inoculations were practical. Contamination of cultures or plates in the field was not apparent. The recovery in 68 samples from wells receiving contamination suggested also that direct examinations were advantageous. The iced samples afforded 68 per cent of the direct recovery of the C-A group as a

whole, and though a comparable number (95.5 per cent) yielded typical *B. coli* due to the gross contamination of receiving wells the C-A count on pour plate approximated only one-tenth.

Quintuplicate Comparison—Table I gives the numerical data for bacteriological analyses of samples in the different groups by the direct method, and compares the findings by the other methods in terms of the direct (percentage).

It is clear that in all groups the time interval before examination is of prime importance in the recovery of organisms of the colon-aerogenes group from water samples. Icing, though of secondary value, in general contributes definitely to recovery.

A. The direct method demonstrates its superiority by slightly higher gas production, significantly greater recovery of the C-A group as a whole, and notably higher yield of *B. coli*, evidenced not only by the greater

| | | | | EI | 85.6 | 45.8 | 45.5 | 44.0 | 14.6 | 96.4 | 86.7 (20) |
| Total | 32 | 64 | 316 | EU | 82.7 | 44.6 | 38.6 | 50.0 [‡] | 44.8 [‡] | 112.3 | 288.8 (99) |

^x Numerical data for D; I, U, EI, EU expressed in terms of D (percentage).

[†] Number in () indicates plates showing counts greater than 1,000.

[‡] Discounting 29 counts from 124 plates in Group 3 not possible to indicate accurately.

percentage of positive samples but by the higher proportion of pour plates showing C-A colonies in greater numbers. There is progressively less recovery by other methods in the order: iced, un-iced, express iced and express un-iced.

B. Recovery from iced samples examined within a few hours is definitely and significantly greater than from the remaining 3 methods under the conditions of fecal or surface contamination usually encountered in the examination of water supplies. In handling samples yielding certain soil *B. aerogenes* only, icing apparently accelerates the death rate.

C. Though the difference in recovery of C-A organisms as a group from iced and un-iced samples held for 24 or more hours is slight, possibly because of the susceptibility of certain *B. aerogenes* to cold temperature, the yield of *B. coli* in favor of the express iced probably is significant.

Of special interest are the findings of 57 samples chosen from Group 3 from wells which, with 1 important exception mentioned later, had been consistently showing fecal *B. coli* derived from latrine contamination over a considerable period of time. With the exception of 1 sample showing gas due to anaerobes, the remaining 56 yielded *B. coli* upon direct examination in all samples, approximately 70 per cent in 1.0 c.c. or smaller volumes. The results are tabulated in Table II.

In these samples the standard iced method offered little better than one-half the direct recovery of *B. coli*, the un-iced express less than one-fourth, while the un-iced and express iced

yielded approximately 33.0 per cent. Pour plates from samples, iced or un-iced, yielded approximately one-fifth of the direct C-A count when inoculated within a few hours and less than one-tenth when samples were held from 24 to 30 hours. In the un-iced express samples the marked loss in red colonies, 4.0 per cent of the direct, is in contrast to the increase in "other" colonies which were more than twice as numerous.

Among these wells one (X) is of particular interest. In contrast to the others this had been giving good water for approximately 2 months while pumping 40 gallons. In withdrawing 240 gallons fecal *B. coli* were pulled into the well, recoverable in all samples tested, yielding 1 to 6 *B. coli* per c.c. in 4 out of the 5 samples by the direct method. In this significant situation typifying a well affording consistently good water which under unusual conditions yielded dangerous contamination, the other methods contributed samples positive for *B. coli*, in 10 c.c. volumes only, as follows: iced 3; iced express 2; un-iced and un-iced express 1 each. A second well of this group showing gross contamination with *B. coli* in all 5 samples by the direct method, yielded *B. coli* also by the other methods, but in significantly less numbers evidenced by C-A colonies on pour plates: (D) 583; (I) 101; (U) 27; (EI) 37; and (EU) 26.

DISCUSSION

These results emphasize the points stressed by *Standard Methods of Water Analysis* that "because of the rapid and extensive changes which may take place in the bacterial flora of bottled waters when stored even at temperatures as low as 10° C., it is urged as of importance, that all samples be examined as promptly as possible after collection." Our series serves to emphasize anew the probable process of loss of bacteria significant of dangerous contamination—a rapid death rate of fecal organisms, particularly *B. coli*, and an increase in associated organisms. The particular wells mentioned support the general findings that in the light of results from direct inoculations the death rate of fecal *B. coli* in bottled waters is very rapid even within a few hours. Our results indicate that in bacteriological analyses of water receiving undoubted fecal and perhaps dangerous contamination the loss of recovery even with the iced samples examined within a few hours approximates 40 to 50 per cent, and there is progressively greater loss as the time of holding increases whether samples are iced or un-iced. It should further be stressed that in the examination of our samples the procedures involved a more thorough search for fecal organisms than usual in public health laboratories, and it follows that our findings probably show greater recovery than would obtain in the analyses of the same samples under routine conditions. Unless samples are inoculated directly, our results indicate the need of icing when waters are receiving significant fecal contamination and suggest that the increasing tendency to send samples un-iced is open to question. Though practical circumstances may make examination of un-iced samples necessary or even advantageous in handling certain waters, it should be emphasized that the practice derives sanction from expediency and does not

conform in general to the conditions best for analysis.

CONCLUSIONS

We have found direct inoculation feasible. There is no question of the marked superiority of this method under any and all circumstances. We believe that with samples collected by state employees, particularly from water supplies of small villages and towns without laboratory facilities, in areas where bus transportation is available to carry cultures and plates to a central or branch laboratory for incubation within a few hours, direct inoculations are practicable. In water plants serving municipalities having laboratories, direct inoculations at the various stations could readily be adopted.

SUMMARY

An analysis of 50 replies received from state and insular laboratories indicates (a) that in most cases the procedure prescribed in *Standard Methods of Water Analysis* with respect to the storage and time of examination of water samples is not observed; (b) that a large number of water samples are not examined within 24 hours and a considerable number after 48 hours; (c) that ice-packing of water samples is rapidly declining. Comparison of recovery of colon group bacteria from iced and un-iced samples examined at varying periods indicates a very rapid death rate of *B. coli* in bottled samples of contaminated waters, which is progressively greater as the period of holding increases. Icing, though of secondary importance, offers a distinct advantage. Direct inoculations were found practicable and showed marked superiority over any other method. The feasibility of the direct method for municipal water supplies is suggested.

Record Forms for Public Health Nursing

IN 1925 the Records Committee of the National Organization for Public Health Nursing drafted a set of nursing record forms so designed that the nurse might work with the family as a unit. The forms were put out with the understanding that they would be revised from time to time to meet the changing needs of the public health nursing field.

These forms have just been revised as a joint project of the American Public Health Association Sub-committee on Record Forms and the National Organization for Public Health Nursing Records Committee. As the forms are to be included as part of the standard forms for public health work to be recommended by the A.P.H.A. Sub-committee on Record Forms, the terminology and general set-up of the records conform to those of the other forms for reporting health work.

The plan of the 1925 Record System has not been changed in this revision; the record forms are again planned to enable the nurse to work with the family as a unit, and, in most instances, they are to be used with the family folder. However, individual records are so designed that it is not necessary to use the family folder and any record may be used by itself.

The significant features of the record forms are:

Provision for a definite content of visit by listing the conditions which must be watched in making an effective visit.

Provision for the minimum amount of writing by the nurse, by listing on the forms the items which may be checked, or by using a code suggested on the record, to give the desired information.

Provision for entering on certain forms, summaries of conditions found and care given, either when the case is closed, or periodically if patient is under care for a long time.

The Record System includes the following forms. An asterisk indicates those forms which have not been changed in this revision.

- Index Card *
- Family Folder
- Maternity Service
 - Maternity Record—AP-Del -PP - NB (double form)
 - Maternity Record (Prenatal Service)
- Morbidity Service
 - Morbidity Record
 - Continuation—Morbidity
 - Record of Care *
 - Tuberculosis Record
 - Tuberculosis—Record of Visit (double form)
- Health Supervision Service
 - Child Health Supervision—Infant—Pre-school (double form)
 - Medical Conference Record *
- Extra Data *
- Nurse's Daily Report *
- School Service
 - School Health Record
 - School Nurse's Record of follow-up
 - Nurse's School Report *

The following is a brief description of the various forms and of the revisions made:

Index Card—This is an individual identification card which is used to determine whether the individual is or has been under care.

The Family Folder—This form is designed to give a complete record of the family. The face of the form provides spaces for entering facts about the social history and the environment of the family. Certain items which are considered necessary only under special conditions are starred to indicate that information regarding these may not be entered for every case. The inside of the folder provides space for a summary of services given to individuals in the family.

It is recommended that a family folder be used for health supervision and when any social or economic problem is indicated. It may or may not be used when there is no social or economic problem.

The only revision on this form is the addition of certain items particularly applicable to rural areas.

Maternity Service—The *Maternity Record*—AP - Del - PP - NB is designed for use during the complete maternity period. Space is provided for entries during prenatal and postpartum care and for facts relating to delivery. Space is also provided for entries on care of the new-born infant during the postpartum care of the mother.

The principal revision in this form is the rearrangement of conditions to be watched for in making an effective visit. Some few items have been added.

The *Maternity (Prenatal Service)* is a new single form designed for agencies, especially health departments, which are interested primarily in prenatal care.

The set-up of this record is the same as that of the maternity record for complete care.

Morbidity Service—The *Morbidity Record* is to be used for care of illness; non-communicable and communicable other than tuberculosis. If used for communicable diseases, information required by health departments may be entered under remarks.

The *Continuation-Morbidity* is the same as the reverse side of the *Morbidity Record*.

The principal change in these two forms is the provision of definite space for entries under "Physician's Orders."

The form *Record of Care* sometimes known as "bedside notes" is to be left in the home and is used by all who are caring for the patient.

The *Tuberculosis Record* is intended for use in all diagnosed cases. It may

also be used for suspicious or undiagnosed adult cases. Such cases should be flagged or otherwise specially marked. Contacts and predisposed cases among children should be recorded on the special health record forms for their age groups, these records also being specially marked.

This form is planned to provide entries throughout the period of illness. Space is allowed on the reverse side for periodic summaries. Yearly summaries are recommended but the interval between summaries will vary according to type of case carried.

The *Tuberculosis Record of Visit* is to be used with the *Tuberculosis Record* and is a double form. The conditions which are to be watched in making an effective visit are listed and space is provided for supplementary notes on conditions, instructions and care given, and for physician's orders. The principal revision of these two forms is the provision for entries on information in relation to family and household contacts.

Health Supervision Service—The form *Child Health Supervision—Infant—Preschool*, is designed to be used for the health supervision of both infants and of children of the preschool age. Three forms, *Child Health Supervision Record*, *Child Health Supervision—Infant—Record of Visits*, and *Child Health Supervision—Preschool—Record of Visits*, have been combined in one double form. The periodic summary which was on the *Child Health Supervision Record* has been discontinued, as it was found to have little value in actual practice.

The first sheet of the new form provides space for identification data, disease experience, and for immunization and tests. Conditions to be noted in making an adequate visit are listed on sheets 2 and 3. The items listed included those applicable to the care of both infants and preschool children.

Space for physician's orders is provided on the 4th sheet. This form may be used either for visits in the home or for visits to a health conference.

The *Medical Conference Record* is for use of physicians at medical conferences. It is expected that a new form will be drafted by the A.P.H.A. Sub-committee on Records.

Nurse's Daily Report Sheet—This is planned to give a picture of the nurse's day and also to serve as a basis for making up the monthly and annual reports on staff activities. A revised draft is now being worked on by the two Records Committees.

School Nursing Service—The two forms, *School Health Record* and *Nurse's School Record of Follow-up*, take the place of the form on School Health Record. The revised School Health Record is designed to give a picture of the health of a school child over a period of years and a summary of the school nursing service in relation to the child. It is expected that this form will follow the child from school to school.

The School Nurse's Follow-up is designed for entries by the school nurse of her services in relation to the school child and for entries of facts regarding the health of the child during the period of a school year. It is intended that at least a yearly summary of this information will be made on the School Health Record. The School Nurse's Follow-up may then be destroyed.

The *Nurse's School Report Sheet* is designed to give a picture of the school nurse's day and also to serve as a basis

for making up monthly and annual reports on the nurse's activities in connection with schools. It is expected to revise this form at some later date.

GENERAL COMMENTS

The record forms just described have been published although they are not copyrighted. It is hoped that agencies in planning their own forms will follow the same general plan as the published ones so that public health nursing records throughout the country will tend to be uniform.

The published record forms, except for the Family Folder and Index Card, are on 5" x 8" bond paper. The index card is a light weight 3" x 5" card. The Family Folder is an 8" x 10" very tough manila folder which folds as a 5" x 8" container in which all the individual case records of the family may be kept.

The forms are available from Mead & Wheeler Co., 610 South Michigan Avenue, Chicago, Ill. The price list and a sample set will be sent directly by them to anyone on request.

DOES HEATING INJURE THE NUTRITIVE PROPERTIES OF MILK?

THE artificial feeding of children and infants is a necessity as well as an accepted fact, as is also the use of cow's milk for the purpose, to the practical exclusion of that of other animals. There are some who advocate the use of raw, some pasteurized, some boiled, and others dried milk, and all of these can give reports which are favorable.

In spite of the extensive literature dealing with almost every phase of artificial feeding and almost every type of milk, there is very little that can be used to make a fair comparison between raw milk on the one hand and heated milk on the other. Volumes have been written on pasteurized milk. Its value in the nutrition of children, in preventing gastrointestinal disturbances, and in stopping epidemics can certainly not be denied. Some experiments are entirely unfair; one, for example, in which a group of 122 infants fed on certified milk were compared with 112 fed on pasteurized milk, both milks having been boiled, is certainly not of much use, since the certified milk was of the highest quality, and the pasteurized of ordinary quality. An experiment on a large scale was done in 1930, in Lanarkshire, Scotland.¹ In this, 5,000 children were given raw milk and 5,000 pasteurized, all of the same grade originally. The investigators concluded that as far as growth, weight, and height were concerned, the results from the two milks were equal. The only clear conclusion which could be drawn from this work was the value of the milk ration in improving the nutrition of the children. The extensive coöperative experiment carried out in this country,² and reviewed in our issue of December, 1932, also showed, as far as it went, that there was practically no difference between the groups fed chiefly on raw milk, and those chiefly on heated milk, as regards the average heights and weights.

In regard to dried milk, which seems to be increasing in popularity, it can again be said that there are no experiments on record which enable us to make a clear-cut comparison between it and pasteurized or raw milk. The changes produced in drying are probably closely allied to those due to pasteurization, though the temperatures reached by the two processes in general use are probably higher than those ordinarily used in pasteurization, and may vary considerably. However, the testimony of experts who have observed the feeding of children with dried milk for many years is that there is no evidence of nutritional loss, so we must believe that the chemical changes do not have much clinical significance.

An unusually clear and judicial study of the question³ points out, what is so well known, but often forgotten, that cow's milk is adapted for the nutritional requirements of calves—not children—and takes the ground that it is perfectly possible that the slight changes produced by pasteurization are beneficial to children rather than otherwise, making it more nearly like human milk. "There is nothing sacrosanct about the composition of cow's milk in relation to man."

The actual changes in milk produced by pasteurization are an increase in insoluble calcium of about 6 per cent, a reduction in the iodine content of about 20 per cent, and some destruction of vitamin C. Milk is not rich in vitamin C at best, though the amount is usually adequate for nutrition, but in actual practice, it is generally supplemented both for raw and pasteurized milk.

In considering the effect of these changes, it may be that pasteurized milk is not as suitable for certain animals whose calcium needs are greater than those of calves, but it seems there is no evidence that this is injurious to infants whose calcium needs are lower. The pasteurization of cow's milk brings it somewhat nearer to human milk as regards available calcium and phosphorus, and the change may be regarded as beneficial. Animal experiments as well as nutritional experiences on a large scale certainly give no support to the idea that pasteurized milk is in any way inferior to raw for infant feeding. These statements may not be entirely true for older children, since they require a greater amount of calcium for bone formation, and this is especially true for those who may be on a diet that is otherwise deficient in calcium, but apparently there is at present not much evidence on which to make such an assertion.

We have an immense volume of clinical evidence gathered from many countries which shows that pasteurized milk has fulfilled the needs for the feeding of infants and children over many years, with no evidence of damage, provided the possible loss in vitamin C is made good. The author above referred to holds that in view of this mass of clinical experience, it is up to opponents of pasteurization to demonstrate nutritional harm done by the process, and points to the fact that such experimental work as has been done proves that they have conspicuously failed to do so up to the present.

When we add to this the marked lessening of intestinal troubles and contagious diseases carried through milk, it is hard to understand how any opposition to pasteurization can be justified.

COMMON SENSE IN HEALTH PROPAGANDA

PRESUMABLY everyone who has studied the question of health propaganda has realized that a certain amount of harm can be done by unwise health preaching. Many people are more or less ill balanced, and just as the medical student, according to the old saying, has for a while every disease which he studies, so do nervous persons suffer from imaginary dangers and diseases. This view is certainly not a new one, since many years ago it was held that writing concerning disease in ordinary language instead of in classical Latin would increase both real and imaginary illnesses.

For some years there has been no lack of medical and alleged medical information given to the public by the daily press. Many organizations which have done a vast amount of good have with the very best intentions put on campaigns for the instruction of the public. Periodical medical examinations have been urged by the highest authorities, and it is hard to doubt that they have had on the whole a good effect. On the other hand, it seems equally certain that some people have been frightened, and that there has been at least a tendency to make the public "disease-conscious."

Apparently the laity may very well question the sincerity of the medical profession in this movement. Though every doctor has capable professional friends always ready to give every examination possible free of charge, how many of them avail themselves of their opportunities? Do the wives of doctors suffering from cancer of breast, for example, come to the operating table sooner than other women? If not, why not? Many clinicians doubt the propriety and value of periodical medical examinations, though recognizing the value of early diagnosis, especially in diseases like tuberculosis, cancer and conditions characterized by albuminuria and high blood pressure.

A thoughtful and wise presentation¹ has recently appeared in which the ground is taken that in this matter of health propaganda, the practitioner and the health officer should work in closer coöperation. There is no question that many of the propositions put forward on this subject come from those who do not know sick people, whether or not they are graduates in medicine. The clinician on the other hand, and especially the old time family doctor, knows human nature and sick people as the laboratory man and the layman can never do, and his advice is correspondingly valuable.

Just how far it is advisable or wise to frighten a person depends largely upon the individual. No less an authority than Sir Thomas Horder has recently said, "Concern about high blood pressure is one of the chief factors in maintaining it, and this holds good whether the concern be on the patient's part or upon the part of the doctor." Another man of long experience has said that many young women are being frightened out of having children. This might have been understood before the days of antisepsis, and though even now maternal mortality is too high, generally speaking, child birth is reasonably safe.

Another instance is the propaganda for early diagnosis of cancer. Many people, especially women, spend their lives dreading cancer. Here there seems little doubt that the propagandists have exaggerated somewhat for the purpose of putting the point over, as well as enlisting the sympathy of the philanthropists in order to raise money for a purpose which unquestionably has a sound foundation.

Our local, state, and federal health authorities must continue to preach public

health and to give out interviews through the press and over the radio. These are now well recognized and widely practised procedures. We may well ask what effect they have had on the general health. The answer is that for most people it has been good, though we recognize that some phobias have been induced.

Many believe that the future control of contagious disease lies largely in prophylactic vaccination, and all over the world, efforts are being made to discover vaccines. Concerning these, when they are discovered, as well as for those for which vaccines are already known, there must be given to the public information accompanied by advice which may be so urgent as to partake somewhat of the character of compulsion. How should such a campaign be carried out? The highest success has been attained by enlisting the aid and coöperation of the family physician—in other words, the clinician. It is a matter of wisdom for the health officer to keep in close touch with those who reach the largest proportion of the population, to consult with them, and to accept their advice. Any antagonism which may be aroused seriously injures the cause which the health officer has at heart, and may result in a large degree of failure, not only for that particular scheme, but for others of like character elsewhere.

DEFEAT OF PASTEURIZATION IN MANCHESTER, ENGLAND

FROM England comes the news that Manchester by popular vote has rejected the compulsory pasteurization of milk. An English journal¹ says that only 13.2 per cent of the electors voted, and yet we are told that this was the heaviest balloting ever recorded on a vote of this description. The editor makes very strong comments on the futility and foolishness of submitting any question of public health to the popular vote, saying very properly that the public is not in a position to understand such matters, not having been trained technically to deal with them. He holds that the Public Health Act of 1875, which is generally regarded as one of the finest pieces of public health legislation ever enacted in the world, would have failed of passage if the provisions had been submitted piecemeal to popular vote, and feels that even today most of them would be rejected if subjected to such an ordeal.

The Manchester Corporation Bill provided that all milk other than certified and Grade A (Tuberculin-Tested) coming into the City should be pasteurized. It is stated that 75 per cent of the milk supplied to Manchester is already pasteurized, that the City Council issued 350,000 explanatory leaflets for the education of the public, and that 323 children are infected with bovine tuberculosis every year, at a cost for treatment to Manchester of \$90,000. In 1929, of a total of 1,133 samples of milk, 111, or 9.8 per cent showed tubercle bacilli. Of mixed milk samples from 697 farms examined during the same period, 88, or 12.62 per cent gave positive results. The corresponding figure for London in 1929 was 7.5 per cent. We have learned from the People's League of Health, as well as from other sources, that some 40 per cent of the herds in England react to the tuberculin test, that 2 per cent of the milch cows have tuberculosis of the udder, and that 14 per cent of market milk yields living tubercle bacilli.

Against such facts, the argument was used that compulsory pasteurization would drive the small producer out of business, that children prefer raw milk, and that it is more nutritious, since pasteurization precipitates calcium and destroys the vitamins. In the face of this, we have a declaration from the Minister of Health that pasteurization "ensures a milk which is not only safe but also retains its food value practically unimpaired." The Public Health Committee of the Town Council approved the Bill submitted and apparently did all they could to have it passed.

In a scathing editorial, the publication referred to¹ makes the statement that if the voters had possessed the requisite technical knowledge, their vote would have been one of censure not only of the health committee, but of their official adviser, the medical officer of health. We are told further that the great majority of distributors in England are now in favor of pasteurization, and that two of the large associations are made up almost entirely of those who pasteurize milk. However, what is described as a small minority was enabled to defeat this measure for the protection of the public, and the Corporation of the City has no alternative than to accept the verdict of this poll.

In 1899, the Corporation of Manchester obtained the passage of a Local Act which gave them power for the control of milk produced outside of the City and suspected of being infected with tubercle bacilli. The "Milk Clauses" were later incorporated in about 100 Local Acts which enabled the authorities to trace infected milk back to the farm from which it came, and to prohibit the sale of milk from animals in such areas. In 1914,^{2,3} these Local Act clauses were repealed, and in 1915, reënacted in the Milk and Dairies (Consolidation) Act, the enforcement of which was postponed on account of the World War until 1925. The procedure finally adopted seems rather cumbersome, but unquestionably protects the public as well as the dairyman. That it was not satisfactory is shown by the figures quoted concerning tuberculosis, by the apparent necessity for the election just held, and by the statement,² "The Manchester Clauses and the provisions of the Milk and Dairies (Consolidation) Act, 1915, which superseded them, appear to have had but little effect upon the incidence of bovine tuberculosis or the sale of tuberculous milk."

There seems to be little doubt that America has progressed further than England in regard to the handling of milk, though apparently we have much less tuberculosis in our herds. Nevertheless, in various parts of the country, fights are being made on the tuberculin testing of cattle as well as on the pasteurization of milk. Indeed, there is an association which is spreading propaganda for the use of raw milk as against pasteurized, in spite of the many proofs of the benefits of pasteurization to the safety and health of the people, especially infants, children and invalids.

INDIANAPOLIS

A.P.H.A. CONVENTION CITY FOR 1933

INDIANAPOLIS, the capital city of Indiana, is situated in the heart of the United States. Its accessibility makes it an ideal location for the Sixty-second Annual Meeting of the Association.

Indianapolis has innumerable points of interest and an historical background of unusual significance to the visitor. The first thing one notices in the downtown district, the Cross-roads of the Nation, is the Soldiers' and Sailors' Monument in the Circle. Erected shortly after the Civil War on the site of the home of the first governor of Indiana, this fine dignified shaft, which is second in height only to the Washington Monument in Washington, is the axis around which the rest of the city rotates, and the observer will note other points in which the city resembles

in appearance and character the national capital. Like the City of Washington, Indianapolis was not born; it was legislated. Seven years after the admission of the state of Indiana to the Union, Indianapolis was selected as its capital, and was surveyed by a competent engineer who had assisted in planning the City of Washington.

Quite the outstanding landscape and architectural feature to be observed from atop the Monument at the present time is the massive structure that has been completed in the center of five downtown city blocks, the Memorial Plaza to Indiana's participation in the Great War, which involves the expenditure of approximately fifteen million dollars. The Memorial proper is a square shrine with a pyramidal dome ninety-six feet high.

Indianapolis is the home of Booth Tarkington, celebrated author and playwright, and Meridian Nicholson, whose fame is equally widespread. William Herschell, the "Indiana Poet," claims Indianapolis as his home, and, too, Indianapolis holds the Shrine to which thousands of children and grown-ups make pilgrimages, the home of the poet, James Whitcomb Riley. It is a modest red brick house on Lockerbie Street, a stone's throw from the Murat Temple and Theatre, one of the largest Masonic structures in the United States. The house contains the furniture which he had used, and his unpretentious, book-lined study recalls memories of his oft-repeated works. The house has been set aside as an Indianapolis institution, and is being preserved to posterity.

Architecturally, Indianapolis ranks among the first cities of the land. The Public Library is conceded to be quite the finest example of severe Greek architecture in America. The Federal Building, which occupies the entire block between New York, Pennsylvania, Ohio, and Meridian Streets; the City Hall, the new Chamber of Commerce Building, facing University Park; the new National Headquarters of the American Legion in the Memorial Plaza; the Indianapolis Athletic and Columbia Clubs; and the National Guard Armory; these and some of the finer business buildings, banks and hotels are far above the level of the usual municipal architecture. The Scottish Rite Cathedral has attracted international attention as a reproduction of Old World architecture. The

Home of James Whitcomb Riley

Indianapolis Motor Speedway

interior is as striking as the exterior. Its central tower is equipped with Carillon bells which are said to be among the finest in America.

Indianapolis has devoted much time and money to the development of an elaborate park system. The Taggart Riverside Park and Garfield Park are worthy of particular attention. The latter's sunken gardens, with their varicolored illuminated fountains, are of great interest to visitors.

Ten miles to the north of the city is Fort Benjamin Harrison, the United States Army Post, which now houses the troops of the 11th Infantry and an aerial squadron; and approximately five miles to the north and west is the Indianapolis Motor Speedway, the greatest track in the world. The Speedway is a two-and-one-half mile brick oval and is to motordom what Churchill

Downs is to lovers of the Derby. It is the scene each Memorial Day of the 500-mile sweepstake which has been responsible for more advances in motor development than any other influence.

Indianapolis has a population of approximately four hundred thousand people. More than two million people live within two hours' ride of it, and more than sixty million more can reach the city over night. The railroads have provided through pullman service from practically every railroad terminal of any size in the United States. Seventeen steam lines, and more than a score of bus lines converge here. Indianapolis acts as a hub to a number of trunk lines including the C. I. & L., Big Four—New York Central, Pennsylvania, B. & O., Illinois Central, and the Nickel Plate Railroads.

Indianapolis is as easily accessible by

automobile as by train. It is the intersection of two transcontinental motor-ing routes of the United States arterial highways systems and the converging points of a number of hardsurfaced national and state roads. The state of Indiana, as a whole, has long been known for her wonderful highway system and has acquired the title of "The Tourists' Paradise." The trans-continental routes are the National Old Trails Road from Washington, D. C., to Los Angeles, and the Pikes Peak Ocean to Ocean Trail from New York and Philadelphia to San Francisco.

There are many things of scientific interest to the health worker in Indianapolis. They will be covered in detail in a subsequent article.

State and local officials are already preparing to receive delegates to the Sixty-second Annual Meeting, October 9-12. They unite in a hearty invitation to members of the Association, their families and friends to attend.

The Local Committee in Charge of Arrangements is an impressive group of medical, health, civic and social leaders all pledged to make the Indianapolis Annual Meeting memorable.

LETTER FROM GREAT BRITAIN

THE FIRST LINE OF DEFENCE

Though here, as elsewhere, the central government health department, the Ministry of Health, is responsible for the conduct of international health relations, ever since 1875, when the line of organization was laid down, the local authorities of the ports actually serve as the first line of defence against the entry of infection.

Sir John Simon, commonly regarded as the founder of the system now in operation, even though for long an officer of the central department, always held that safety would best be secured by leaving the work in the hands of the local authorities, empowering them to make all the necessary provision in the shape of hospitals, etc., the responsible minister issuing from time to time such rules, orders, and regulations for their guidance as appeared to be required. Power to the health minister to make orders, etc., alone or in consultation with other departments—the Admiralty, the Foreign Office, etc.—was given in the Public Health Acts.

At intervals new regulations have

appeared incorporating new views, the result of progress or based upon decisions arrived at in international conventions, and so on, and the authorities at the ports and their officers have carried them out most effectively and efficiently.

The most recent to appear are the Port Sanitary Regulations, 1933. These were issued about the middle of February, and come into operation on May 1, 1933. Intended primarily to replace and consolidate certain orders and regulations made from time to time between 1907 and 1929, they include also provisions for carrying out obligations assumed under the International Sanitary Convention of Paris, 1926, for preventing access of rats to ships, and for the control of persons embarking in outward-bound ships who are suffering from infectious disease or who have been in such relations with persons so suffering as to render them liable to transmit the disease. Modern methods of international interchange of information relating to epidemic diseases are taken into account, and special measures are prescribed for

dealing with ships infected with typhus fever and smallpox, in addition to those infected with plague, cholera, or yellow fever, three diseases to which for long special regulations have applied. In addition to imposing duties upon the authorities, the regulations also lay down those to be performed by ship masters, customs officers, and the medical personnel of the local authorities at the ports.

The arrangements under which persons aboard foreign-going ships found to be infected on arrival are permitted to proceed to their destination, on providing particulars as to their movements and the address to which they are proceeding, for the information of the health officer of that area, are continued. Having regard to the fact that this system has proved eminently workable and a perfect alternative to quarantine of the older type, it is not surprising that it should have been continued.

VOLUNTARY MEDICAL AND SURGICAL SERVICES IN LONDON

A report of a survey of medical and surgical services in London, undertaken jointly by the London Voluntary Hospitals Committee and the London County Council, recently issued, contains an amount of information of distinct value and interest. The first part, for which the former body is responsible, contains reference not only to hospitals but to voluntary clinics and dispensaries.

So far as hospitals are concerned, these are divided into four groups: teaching hospitals (St. Bartholomew's, Middlesex, Guy's, etc.); other general hospitals containing a hundred beds or more; those containing less than 100 beds; and special hospitals.

In all, in the voluntary hospitals there are 14,833 beds. The total number of new in-patients treated in the year 1931 was 216,788. Of these, and

in respect of whom information is available, 134,752 came from within the county of London, and 79,385 from outside the county. The proportion from outside the county is naturally greater in the case of the teaching hospitals, namely, from inside the county 59,307, and from outside 36,740. The same is true of the special hospitals, with 46,385 from the county, and 29,702 from outside.

The population of the county of London in 1931 was 4,397,003. The population of Greater London was 8,202,818.

Some indication of the work done in relation to in-patients is given by the fact that the voluntary hospitals have 239 operating theatres, and in one year 123,312 operations were performed on in-patients. New out-patients amounted to 1,596,361, and the total out-patient attendances in 1 year was 8,355,756, a number greater than the population of Greater London.

The information collected with regard to voluntary dispensaries is difficult to summarize, but speaking generally there appears to be in the London area a quite astonishing assortment of institutions of this type and very ready of access, more particularly from the poorer quarters in the different areas of the metropolis.

Municipal Hospitals, Clinics and Dispensaries—In part II, which treats of municipal hospitals, clinics and dispensaries, it is shown that in regard to the two last-named, the metropolitan borough councils have not been ungenerous, the provision including, in addition to tuberculosis dispensaries, infant welfare clinics, and such like standard institutions, clinics, for a wide variety of other purposes—diphtheria prevention, massage, etc.

So far as hospitals are concerned, the survey (part II) gives detailed information of the medical, surgical and other services provided in 1931 by the

council at the 79 general and special hospitals, convalescent hospitals, institutions and other places with beds for patients, and the 49 dispensaries (out-door medical relief stations) under the management of the central public health committee of the council; at 8 of the 13 institutions under the management of the public assistance committee, in which are accommodated, for the time being, a number of chronic sick and other cases; and at the 20 mental hospitals, colonies, homes and institutions for the mentally defective under the management of the mental hospitals committee.

The number of beds for sick persons in the council's hospitals and institutions (apart from mental hospitals) on December 31, 1931, was 38,945. The total number of new in-patients treated in the year 1931 was 201,899. The total number of in-patients treated, based on discharges and deaths, in the year (excluding one convalescent hospital for which the figures are not available) was 210,074, of which all but 5,535 were resident in the county of London. New out-patients in 1931 (excluding special hospital cases) numbered 44,450, and the total out-patient attendances at all hospitals in the year was 259,036.

The total number of beds in the council's mental hospitals, colonies, homes and institutions under the management of the mental hospitals committee was, on December 31, 1931, 32,265.

Home and School Medical Services

—In addition, there is provided a district medical service (*i.e.*, medical attendance on the sick poor who are not in receipt of indoor medical relief) and medical inspection and treatment for school children. The former is carried on by 100 part-time district medical officers and, in 19 of the 119 districts into which London is for the purpose divided, by whole-time officers of the

staff of the council's general hospitals.

Patients are visited in their own homes by the district medical officers or seen by them at the 49 medical relief stations, or, in 21 districts, at the private surgery of the district medical officer. The number of domiciliary visits paid by district medical officers during the year 1931 was 65,604, and the number of attendances of patients at medical relief stations during the year was 257,910.

The council's scheme for school children includes agreements with voluntary committees, who have, at the instance of the council, provided 73 treatment centers, and with the authorities of 17 voluntary hospitals. The numbers of children treated under these arrangements in 1931 were, for minor ailments 106,072, for vision 44,686, for defects of the ear, nose and throat 20,703 (16,243 operations), and for dental defects 139,723, a total of 311,184.

The two parts of the survey bring into focus the whole of the hospital and associated provision made by voluntary agency and public authorities for the population of London. More important still, largely as a result of the setting up of the voluntary hospitals committee and the making of the survey, there has come about a better understanding between the two bodies, with promise of a greater degree of coöperation in the future with growth of mutual knowledge, and a mutual appreciation of the needs of each system.

One most important development, of which there are already indications, is that there will be made available for teaching purposes a great deal of the material in the municipal hospitals which the clinical teachers, if in fact they knew of its existence, formerly considered entirely out of their reach.

CHARLES PORTER, M.D.

London

ASSOCIATION NEWS

NEW MEMBERS

The following list includes applicants who have been approved for membership in the A.P.H.A. by the Sub-Committee on Eligibility. These new members have requested affiliation with the sections indicated, and action by the Section Council will follow.

Health Officers Section

- Horace E. Duncan, M.D., Court House,
Dallas, Tex., County Health Officer
Frank J. Jirka, M.D., 3202 W. 22 St., Chicago,
Ill., Director of Public Health of Illinois
Eli M. Morehouse, M.D., Yankton, S. D.,
City Health Officer
Robert R. Robinson, M.D., 204 S. Garth
Ave., Columbia, Mo., Boone County Health
Officer

Laboratory Section

- Louis H. Burgwald, B.Sc., Ohio State Uni-
versity, Columbus, O., Instructor in Dairy
Sanitation
Arch H. Morrell, M.D., 18 Weston St.,
Augusta, Me., Director, State Diagnostic
Laboratory
Carl Wilson, D.Sc., 207 S. Broadway, Los
Angeles, Calif., Director of Sanitation,
Department of Water and Power

Public Health Engineering Section

- Robert N. Clark, C.E., 74 Eiseeman Ave.,
Kenmore, N. Y., Sanitary Engineer
Charles D. Yaffe, M.S., 2830 Grant Ave.,
El Paso, Tex., City Sanitary Engineer

Food and Nutrition Section

- Davis W. Fountain, City Dairy Dept., City
Hall, Phoenix, Ariz., City Milk Inspector
Mrs. Gustavo Saliva Soria, Box 38, Marina
Station, Mayaguez, P. R. (Associate)

Child Hygiene Section

- Frederick L. Patry, M.D., State Education
Dept., Albany, N. Y., Neuropsychiatrist

Public Health Education Section

- Mary S. Close, A.B., High School of Com-
merce, San Francisco, Calif., Science
Teacher
Harry L. Hopkins, 386 Fourth Ave., New
York, N. Y., Director, New York Tubercu-
losis and Health Association
Katherine Sarabia, S.B., Massachusetts Inst.
of Technology, Cambridge, Mass., Research
Assistant in Health Education

- Elvessa A. Stewart, A.B., Manila, P. I., Chief,
Dept. of Home Economics, Bureau of
Education.

Public Health Nursing Section

- Alice F. Mitchell, Colchester, R. F. D., Conn.,
Secretary, Salem Public Health Nursing
Association
Nora Moore, 22 Prince Arthur Ave., Toronto,
Ont., Canada, Acting Director of Public
Health Nurses, Dept. of Public Health
Grace W. Pinckney, R.N., 608 City Hall,
Omaha, Nebr., Supervisor of School Nurses
Carolynn S. Whiting, R.N., P. O. Box 78,
Phoenix, Ariz., Public Health Nurse

Epidemiology Section

- John E. Laxton, M.D., D.P.H., Dept. of
Public Health, City Hall, Toronto, Ont.,
Canada, Director, Division of Com-
municable Disease

DECEASED MEMBERS

- Howard A. Lanpher, M.D., Des Moines, Ia.,
Elected Member 1923, Fellow 1932
Charles B. Maits, M.D., Pittsburgh, Pa.,
Elected Member 1929, Fellow 1932
Harry K. Read, M.D., Houston, Tex.,
Elected Member 1928, Fellow 1931
C. A. Shore, M.D., Raleigh, N. C., Elected
Member 1909, Fellow 1923
Leonard M. Wachter, Albany, N. Y., Elected
Member 1906, Fellow 1922
Albert L. Brannock, M.D., Pontiac, Mich.,
Elected Member 1925
Margaret M. Butler, Chicago, Ill., Elected
Member 1928
Louis Cantor, Jerusalem, Palestine, Elected
Member 1926 (Associate)
Anton J. Cermak, Chicago, Ill., Elected Mem-
ber 1926
A. A. Crooks, M.D., Peoria, Ill., Elected
Member 1925
Charles R. Grandy, M.D., Norfolk, Va.,
Elected Member 1907
Sylvan McElroy, M.D., Orlando, Fla.,
Elected Member 1927

PUBLIC HEALTH ADMINISTRATION

HEALTH DEPARTMENT REPORTS

THIS section received more annual reports for 1932 during the first two months of the new year than heretofore. One of the values of the annual report depends upon its timeliness, hence the tendency for early issuance of these documents is commendable. While some of these reports have occupied less space than formerly and have omitted some of the routine statistical tables, they have in general been more carefully planned and more interesting to the average reader. Among the early reports are those for Colorado Springs, Detroit, Palama Settlement (Honolulu), Palo Alto, Pasadena, Middletown, O., Lincoln, Neb., Steubenville, O., Chicago, Peoria.

Colorado Springs—While an increase in the general death rate for the city is noted for 1932, this did not occur in tuberculosis nor in other common communicable diseases. The greatest increase was noted for the circulatory diseases, followed by certain respiratory diseases. Infant mortality was somewhat higher in 1932 than in 1931, the infant deaths from prematurity being most marked. There were 3 cases of diphtheria with no deaths in this city of 33,237. One of the increased problems associated with the depression is said to be that of supervision of the milk supply and of preventing the sale of "bootleg" milk. Increased efforts were necessary to discover and inspect the establishments of unlicensed milk dealers.

Palama Settlement, Honolulu—In Honolulu, the health and welfare center, known as Palama Settlement,

maintained its watchword of "Prevention as well as cure" in 1932 and adopted the goal of "more work at less cost." Palama public health nurses increased home visits to 45,708, almost 9,000 more than in 1931. The doctors and dentists treated 78,629 cases, an increase of more than 11,000 over 1931. The newly organized Tuberculosis Committee carried the message of prevention to tens of thousands of island residents on Oahu, Maui, and Hawaii.

One-seventh of the energies of this center is devoted to recreation and the department served 15,000 of all ages. These services include: club activities, boy and girl scouting, home-making, physical education, swimming, athletic leagues, and social dancing. The center reached through all its services 200,000 during the year. An attractive, beautifully illustrated 4-page report tells the story.

A more detailed report of dental services shows that the Strong Foundation contributed some \$30,000 to provide high grade dental treatment to 6,552 children, representing 57,396 treatments. These were children attending the first 5 grades of the public schools whose parents were unable to pay for private dental care. There were also 7,155 elementary public school children in the city who were under the care of private dentists. Only 6,184 children received no dental care. On the average, the cost of complete dental care per child, necessitating 3 visits each, was \$4.01.

Palo Alto, Calif. — In presenting his 1932 report to the Board of Public Safety, the Health Officer of Palo Alto

made the following significant comments:

Those activities which make for economy and efficiency possess the greatest opportunity to survive the readjustments through which governmental agencies are passing. True economy consists not so much in minimal outlays as expenditures that constitute sound purchases or investments. Often false economy results from failure to make the proper expenditure. . . . The best investment the community can make is in itself, its children, mothers, and citizens. . . . The city of Palo Alto has definitely been engaged in the public health business since 1910 when the full-time department was started. Each year since that time she has invested certain sums of money in her citizens in the shape of appropriations to the health department. The returns on these investments are set forth definitely and unmistakably in the annual reports of the department.

For the period 1910-1932, the average infant mortality rate was 41.6, or about half that for the state, and in 1932 the rate was 20.5. About 58.6 per cent of the school children and most of the babies have been immunized against diphtheria. There has been but 1 death from diphtheria since 1911 and none since 1921. A high grade milk supply is provided, with no milk-borne disease recorded in years. Laboratory service is available through the coöperation of the Palo Alto Hospital and the Health Department.

In 1931, Palo Alto was again an honorable mention city in the U. S. Chamber of Commerce Health Conservation Contest. Expenditures for health by all agencies amounted to \$1.30 per capita. It is observed that the 5 honorable mention cities in California expended in 1931 an average of \$1.94 per capita for health as compared with \$1.12 per capita for the 13 cities in the state in the contest which did not receive awards.

Pasadena, Calif.—The 1932 Health Department report of 103 mimeographed pages is well prepared and effectively illustrated. Reports of

coöperating agencies as well as of the Health Department are included, Pasadena has obtained honorable mention each year in its population class in the annual Health Conservation Contest of the U. S. Chamber of Commerce. The infant mortality rate of 34.9 and the maternal mortality rate of 3.7 are worthy of note. In connection with prenatal care, an arrangement has been made with attending physicians and local hospitals to furnish Wassermann tests without cost. Four conferences on maternal and prenatal care are maintained in this city of 80,000. During the year a careful study of the maternal care service was conducted and a community program was developed with the social agencies.

A survey conducted by the Los Angeles County Welfare Department, in which area Pasadena is located, indicates that there has been an increase of 30 per cent in the incidence of tuberculosis among persons under welfare care since the depression. The city tuberculosis program, through coöperation of several agencies, meets *Appraisal Form* standards.

The report calls attention to the work of 26 members of the Woman's Civic League who served as deputy food and milk inspectors without compensation during the year. Another interesting feature of the report is the rating schedule of the U. S. Chamber of Commerce properly filled out for Pasadena.

Detroit, Mich.—Under the title *Public Health in a Year of Stress* appears Detroit's annual Health Department report for 1932. That a new low general mortality rate of 8.7 and a new low tuberculosis rate of 70.3 were established, together with freedom from smallpox, is noteworthy. The diphtheria death rate of 4.3 is contrasted with that of 6.3 for 1931. There were but 57 cases and 9 deaths from typhoid fever, giving a death rate of 0.6. Also

commendable is the infant mortality rate of 52.3, which is less than half of the rate for 1920.

The question may well be asked as to why health conditions have been so good. It is true that, by and large, the death rate throughout the United States has reached a new low figure. Health departments have materially expanded their services during the past two decades; have extended their activities in the prevention of such diseases as smallpox, typhoid fever, and diphtheria, for which known prophylactic means are available; and have extended their activities to find the early case of tuberculosis, provide adequate diagnostic facilities, search for contacts and provide more adequate hospital and sanatorium facilities for known cases. Detroit now has two hospital beds for tuberculosis for each annual death and for the first time the list of those seeking admission has been eliminated. Health education has brought the message of positive and vigorous health, the value of the periodic health examination, and the need for early and prompt diagnosis to the attention of our citizens. It has taken years to stimulate this interest in positive health habits and it is reasonable to conclude that this widespread educational influence cannot be destroyed over night. In 1932 we continued to reap the benefit of the public health program which had been constructed during the past 20 years. The health of a community reflects the personal health of the individuals who constitute that community and the death rates are an indication of the health consciousness of our citizens. By force of circumstances many people have been deprived of those luxuries and extravagances of life which create over-indulgence and are not considered essential to health and well-being. They have been conserving those fundamental principles which assure a good health tone. Furthermore, the past year has been free of those epidemic diseases for which public health administration does not possess precise means of control. There has been no widespread outbreak of influenza with complicating pneumonias. We have lived more sensible lives with no excesses due to over-work and our daily habits have been seasoned with reasonable amounts of recreation, lack of over-indulgence in unnecessary foods, and freedom from excessive extremes in our mode of living. Briefly then, our new health record may be attributed to a general understanding of the principles of hygienic living coupled with such prophylactic services as are at our disposal and blessed by the

absence of epidemic disease concerning which we know little.

In January, in order to balance the budget for the fiscal year, it was necessary to make certain curtailments in the program. It was deemed advisable to conserve those services which deal with the control of the acute communicable diseases, tuberculosis, and the venereal diseases, and the promotion of positive health for the mother, infant, and young child. As cuts in service became inevitable it was decided to curtail those activities which pertain to the higher age groups, especially those activities which might be replaced through the coöperation of other agencies. Consequently, the school dental service was eliminated in January with the exception of the director. The service has been maintained through the aid of the District Dental Society by 300 dentists who volunteered to conduct the dental examinations in the schools and by 60-some dentists who have manned certain of the treatment clinics. In October, the Children's Fund of Michigan appropriated \$25,000 for dental relief and since that date has given emergency dental service in school clinics.

In January, the paid physicians who had conducted the physical examinations in the schools were eliminated and this service has been continued by the Wayne County Medical Society, which through an appropriate committee has officially joined hands with the Board of Education and the Department of Health in providing such examinations. One hundred physicians have donated their services and are giving on an average of one morning each second week. This work is directed through the County Medical Society by the director of the School Health Service who is still employed by the Department of Health on a full-time basis and likewise serves as secretary of the special committee of the medical society. Thus, these two services which by force of circumstances have been eliminated from the health department budget have continued to operate through the generosity of the physicians, dentists, and the Children's Fund of Michigan.

There have been no other major curtailments in service. The communicable disease activities have been maintained at full strength. The tuberculosis and venereal disease clinics have carried a heavier load than heretofore and there has been no relaxation in the services in maternal and infant hygiene. In August, all municipal departments were placed on a 5-day work plan, the employees engaged for 5 full days of the week, the majority not working on Saturday. The Health Department has, however, continued

to function 7 days of the week, those who are employed on Saturday and Sunday being granted appropriate relief on other days. The first curtailment in compensation was made in January with a reduction of 10 per cent in wages and for all receiving more than \$4,000 annually, an additional 10 per cent. With the inauguration of the 5-day plan in August, an additional 14½ per cent reduction in salary went into effect. These reductions are carried in the budget as a salary suspension, there having been no reduction in the basic salaries. The public health nursing service of the department, so essential to efficient work, has been maintained at full personnel. Minor adjustments in certain activities have been made so as to maintain so far as possible the more fundamental services of the department.

In the face of these circumstances, the report properly raises the question of what the future may hold. If the city is deprived of existing facilities for searching out the early case of tuberculosis, the follow-up work of the public health nurse, adequate beds for hospitalization of the advanced case with positive sputum, which is a source of danger to child contacts, beds for the early case which can be arrested and reclaimed, there would inevitably follow an increase in the tuberculosis rate. Other examples are cited. Foremost in the services of the health department is considered the public health nursing personnel which has become the unit through which the health educational program is disseminated. The various health and social agencies are working closely together and the private physicians are participating actively in the preventive program.

Among the important activities of the year are described administrative and epidemiology studies of scarlet fever, a survey of over 200,000 children below 15 years of age as to the degree of diphtheria protection, health education procedures, the introduction of a new strain for tubercle bacilli, the preparation and distribution of convalescent serum, the introduction of

milk on the city market fortified with vitamin D, and special measures for the education of food handlers. The last two pages of the report are devoted to a classified tabulation of health appropriations and to the number and distribution of personnel according to functions.

New Mexico—*The New Mexico Health Officer*, a quarterly bulletin of the Public Health Bureau, presents on its front cover a map of the state, with county divisions. Red dots on a yellow background effectively portray the location of 248 smallpox cases reported during the past 3 years.

According to a study reported the states which require vaccination before a child may enter school, had an average case rate per 100,000 of 9.5 for the years 1921–1926. The group of states in which laws make required vaccination impossible, had an average case rate of 102. In New Mexico, where vaccination is required, the average case rate in 1930–1932 was 20.9, but the 8 Texas borderline counties and one other had a case rate of 47.4. The remaining counties had a rate of 8.5.

The annual bureau of public health report for 1931–1932 omits detailed statistical tables, but effectively uses summary tables with interesting descriptive text. In recognition of the importance of treating syphilis cases, a portion of the financial aid received by the state from the Reconstruction Finance Corporation has been set aside for the purpose of buying drugs for treatment of indigent syphilis cases. Some doctors will give their services free for the work. The New Mexico Social Hygiene Association was formed during the year.

This annual report deserves credit for an interesting discussion of popular health education. Although no allowance was made for the work by the

Legislature, efforts to extend this service were made by the bureau "believing that it is a fundamental service to the people of the state." A newspaper service, with weekly articles, was inaugurated. Through the coöperation of the modern language department of the State University, these articles were also translated into Spanish for newspapers published in that language. Weekly talks were given over the radio. An effective monthly mimeographed bulletin was published as a medium of exchange for the ideas and experience of county health workers. Classes in public health were continued in university summer sessions. Public addresses were frequently given before men's and women's clubs, and a large quantity of health literature was distributed.

Illinois—The general health of the people of Illinois for the past 3 years has been distinctly superior to that which prevailed during any corresponding period in the history of the state, according to the report of the State Department of Public Health for the period July 1, 1930–June 30, 1932. The general mortality rate from all causes for the 3 years ended with 1931 was the lowest on record in Illinois for such a period. The decline in the infant death rate since 1928 has preserved over 4,000 infant lives which would have been lost had the most favorable conditions of any previous period prevailed. Declines in the tuberculosis, diphtheria, typhoid fever, and diarrheal diseases have been significant. Fully $\frac{1}{2}$ million children were immunized against diphtheria compared with 300,000 during the previous 4 years. A survey covering 1 per cent of the population of the state was made to determine the completeness of reports of communicable disease.

The educational work of the depart-

ment has been maintained on a high level. Through numerous public addresses, periodicals, special bulletins, radio, and newspapers, the public has been informed of matters of current health interest, warned against potential or approaching danger, and advised concerning preventive possibilities and timely precautions. Education exhibits have been developed. As a practical demonstration in sanitation, the Department of Health, with the coöperation of the Department of Agriculture and the State Fair management, undertook to make the Illinois State Fair a model project of the kind in respect to sanitary and hygiene matters. This involved the elimination of all insanitary conditions and practices and the medical examination of all food handlers. One typhoid fever carrier, engaged as a dish washer, was detected and removed from that occupation, thus eliminating a potential source of much illness.

Steubenville, Ohio—During 1932 there was an attendance of 499 infants at baby conferences, or double the number of the previous year. In coöperation with the local medical society, the Kiwanis Club, and school health service, the health department gave immunization treatments to 327 first grade children (45 per cent) against diphtheria. Public health nursing services numbered over 10,000. In this city of 35,422, an infant mortality rate of 64 is noted.

The 17th anniversary of National Negro Health Week was observed in April by all local colored organizations. The Booker T. Washington health unit was formed for the strict annual observance of this health week. General meetings in the recreation center and in local churches were held, health literature was distributed, and health talks given. The annual report, although mimeographed, is effectively illustrated.

LABORATORY

WHOOPIING COUGH PLATES IN A PUBLIC HEALTH LABORATORY*

EDMUND K. KLINE, DR.P.H., F.A.P.H.A.

Director of Laboratories, Cattaraugus County Department of Health, Olean, N. Y.

IN an article published in 1916 Chievitz and Meyer¹ of the Danish Sero-therapeutic Institute described a method of obtaining cultures of *Hemophilus pertussis* from whooping cough patients through "seeding by projection of droplets" crediting the method to the suggestion of their "young colleague M. Emile Mauritzen." This method, commonly called the cough plate method, consists of holding a plate of suitable medium about 5 or 6 inches in front of the mouth of a coughing patient during a paroxysm to catch the material expelled from the deeper parts of the respiratory tract. In case the patient is not having actual paroxysms a series of deep coughs is induced. This method has proved of great value for the diagnosis and study of whooping cough in the hands of Danish workers over a period of several years. It was first used extensively in this country by Lawson and Mueller² of the Commission for the Study of Whooping Cough at the Boston Floating Hospital in 1925-1926 with favorable results, and more recently has been highly recommended by several authors, especially Sauer and Hambrecht³ in this country, Gardner and Leslie⁴ in England and Debre⁵ and his coworkers in France.

Since studies of the epidemiology of

whooping cough in large centers of population are necessarily confused by the many ramifications of the contacts of individuals, a series of studies of whooping cough outbreaks in strictly rural areas was projected a few years ago by members of the staff of the Cattaraugus County Health Department in coöperation with the Division of Research of the Milbank Memorial Fund. Studies of one such outbreak in the spring of 1931 have been reported upon by Burroughs.⁶ Reports of further studies during the fall and winter of 1931-1932 are now in preparation. Cough plate examinations were begun toward the end of the first outbreak and continued throughout the studies. The general plan of procedure in these studies was for a field investigator to make contact with all families in the area selected for study, to gather complete data on all respiratory disturbances appearing among the entire population of the district, and to obtain a complete history of all contacts between the various individuals in this population. For this purpose the investigator made semi-weekly visits to each household and school. On these visits cough plates were obtained from all susceptible children in the schools and also from a selected group of other children and adults comprising about one-third of the residents in the area and chosen to represent a cross-section of the population. As soon as a case of whooping cough was recognized, all the immediate contacts of this case were

* Presented at the mid-year meeting of the New York State Association of Public Health Laboratories. Albany, N. Y., November 4, 1932.

added to the list of persons from whom semi-weekly cough plates were collected.

The plates used in this study were prepared in the laboratory using essentially the original Bordet-Gengou formula⁷ with human blood. Due to economic conditions we were able to obtain human blood for a reasonable sum, paying \$5 for each single bleeding which yielded from 500 to 800 c.c. of blood. Defibrinated rather than citrated blood was used. All plates were inoculated less than 1 week after being prepared. After inoculation in the field they were sealed with a rubber band and brought into the laboratory the same evening. They were then incubated and examined each day for 5 days. If *H. pertussis* was present small mercury droplet colonies appeared in from 2 to 5 days. The appearance of these colonies was quite characteristic and the speed at which they developed after they first could be seen was remarkable. It was nothing unusual to examine a plate with a hand lens on one day, fail to find any evidence of growth, and yet on the next day find the plate studded with colonies from 1 to 2 mm. in diameter. We encountered some trouble from spreaders but little from the ordinary saprophytes of the respiratory tract which usually grew readily in the first day and thereafter enlarged very slowly. It was our practice to cut out, as soon as they were discovered, any colonies which looked as though they might spread, but frequently we would find a plate completely covered with a spreader.

The chief bacteriological difficulty in confirming the presence of *H. pertussis* lies in the fact that colony and individual morphology may easily be confused with that of the closely related Pfeiffer bacillus, *H. influenzae*. For this differentiation we made use primarily of the established difference of the two organisms in their growth characteristics on chocolate agar and

blood agar. Transplants of all suspicious colonies were made to tubes of Bordet-Gengou agar and of chocolate agar.⁸ The bacillus of influenza grows readily on chocolate agar within 24 to 48 hours while freshly isolated pertussis organisms fail to grow in 4 days, or the growth is so scanty as to be scarcely visible. On Bordet-Gengou agar the influenza bacillus grows as a flat colony with irregular outlines while pertussis has the characteristic mercury droplet appearance. If the suspected colonies seemed to be *H. pertussis* by these differential media, smears were made from the agar slants, stained and examined to determine if the morphology of individual organisms corresponded with that of *H. pertussis*. In our studies all plates that showed colonies that answered these differential tests were called positive.

A total of 1,996 plates were examined of which 14 per cent were unsatisfactory. Of 343 plates taken from clinical cases in all stages of the disease 22, or 6.4 per cent, were positive. Five additional positive plates were obtained from individuals classed as carriers so that our entire series showed 1.4 per cent positives.

The number of colonies of *H. pertussis* on our positive plates varied from 1 to 100. There was little correlation between the stage of the disease and the number of colonies—single as well as large numbers of colonies (over 50) being obtained from all stages of the disease. We must remember, however, that the inoculation of these plates is a variable technic and that probably the number of colonies more nearly represents the success of obtaining material from the deeper parts of the respiratory tract than it does the actual number of organisms expelled.

Table I lists the plates taken from cases of clinical whooping cough in relation to the stage of the disease. We found one instance in which we ob-

tained a positive plate in the week preceding the first catarrhal symptoms of the disease. The highest percentage of positive plates was found in the week beginning with the day of onset. A gradually decreasing percentage occurred during the next 3 weeks. No positive plates were obtained after the 4th week of the disease.

Table II shows the positive plates in relation to the number of individuals furnishing them. We found that semi-weekly plates taken through the first 3 weeks of the disease were sufficient to give positive results in 93 per cent of our cases. It is obvious that if plates were taken 4 times a week or daily our chances of raising this figure to 100 per cent would be increased.

These findings are in general agreement with those of other investigators.

Chievitz and Meyer¹ in a series of 32 cases obtained 84 per cent positives in the week of onset and 71 per cent in the next 2 weeks, with no positives after that period. Sauer and Hambrecht² in a series of 200 cases obtained 98 per cent positives in the week of onset, 65 per cent from the 2nd to the 5th week and no positives thereafter. McGee³ in a series of 35 cases obtained 56 per cent positives in the week of onset, 63 per cent in the 2nd week, 71 per cent in the 3rd week and 17 per cent in the 5th week. Marie¹⁰ in a series of 48 cases obtained 88 per cent positives in the week of onset, 55 per cent in the 2nd week, 50 per cent in the 3rd week and none thereafter. Gardner and Leslie⁴ in a series of 47 cases obtained 75 per cent positives in the week of onset, 67 per cent in the 2nd week, 75 per cent in

No positive plates were obtained after the 4th week following onset.

the 3rd week and 25 per cent in the 4th week.

All of the cases from which we obtained positive plates would have been diagnosed as whooping cough by clinical manifestations alone. However, in certain cases positive diagnoses could be made by cough plates before clinical symptoms were decisive. Although it requires a minimum period of 7 to 10 days to render a laboratory report on a cough plate, we find that the time elapsing between the first prodromal symptoms and the date on which a positive diagnosis could be made by clinical symptoms alone averaged about 14 days for our series of 16 cases. Actually there were 5 cases in this series on which the laboratory reported a positive plate before the final diagnosis could be made.

We also found positive cough plates from 4 persons who did not develop any symptoms characteristic of whooping cough and who were classed as carriers. These findings have recently been reported in detail by Burroughs and Kline to the American Public Health Association in Washington. The epidemiological evidence of our studies convinced us that these carriers were not responsible for any additional infection and that they are probably of

little consequence in the spread of the disease. Post-convalescent carriers were not found.

The possibility of detecting missed or atypical cases by means of cough plates has frequently been asserted in the literature. There were only 2 additional cases in the area studied which could be classified as probable sub-clinical whooping cough, and the laboratory did not obtain plates from either of these individuals before the 2nd week following onset. All plates from them were negative. As in the case of carriers there was no epidemiological evidence that these sub-clinical cases were in any way responsible for transmitting infection.

On the other hand, there were many persons in the area studied who during the course of our investigations developed some respiratory symptoms, usually suggestive of common colds. We have epidemiological histories of 130 residents of the community not included in the above groups of whooping cough cases or carriers. Although 71 per cent of them showed some respiratory disturbances no positive cough plates were obtained from any of these persons. Many negative cough plates were obtained from them, including 434 plates from 46 persons dur-

also tends to minimize the importance of the rôle played by sub-clinical cases in whooping cough outbreaks.

DISCUSSION

In considering our experience in connection with the question as to what place the cough plate procedure should be given in the program of a public health laboratory we are at once struck with the uncertainty of the method. Repeated negative cultures have been obtained from patients in the early stages of the disease. On the other hand, the identification of 93 per cent of our cases by the cough plate method has been quite satisfactory. It would seem that the first requirement for diagnosis should be that repeated plates be submitted at frequent intervals early

in the disease. We would recommend daily plates. In the next place it is also apparent that errors in the technic of inoculating plates will greatly modify the result. Therefore, it might be well to make the additional requirement that all plates be inoculated in the presence of some person with special knowledge of this procedure. With these two safeguards, the cough plate method may well be included in the program of a

public health laboratory as a means of the diagnosis of whooping cough.

We have shown that the method may serve to detect carriers and it seems quite likely that sub-clinical cases would also have been detected had sufficient plates been submitted at the proper stages of the infection. However, the practical value of detecting either carriers or sub-clinical cases is not established since epidemiological evidence indicates that neither of them are of significance in the spread of the disease.

We know of no application of laboratory findings that would aid in controlling the course of the disease in individuals.

As a means of release from quarantine the findings by cough plate methods seem to be of very little value. Comparison of results with the findings of various investigators using the sputum method of isolating *H. pertussis* show that the latter method is much superior toward the end of the disease, although not so satisfactory in the early stages. Neither method approaches the degree of accuracy necessary in quarantine release technic where dependence must be placed on negative findings.

The most important value of the more general use of cough plates is the research value. There are many disputed questions concerning whooping cough and a large series of cough plates from many laboratories would do much to answer them. For instance, we might be able to rationalize our present quarantine requirements. There are also many important bacteriological questions to be settled. Weill¹¹ and Debre¹² indicate that the organisms lose their virulence during the course of the disease. The serology of the group is not completely worked out and but little study has been made of dissociation variants.¹³ The accessory food factor requirements of other

species of *Hemophilus* have been the subject of some recent investigations, which should be broadened to include the entire group.

Considering all of the above factors it would seem to us that at the present time cough plates are of greater importance to the research than to the routine public health laboratory.

CONCLUSIONS

In times of epidemics of whooping cough the routine public health laboratory can be of considerable service to the physician and to the community in occasionally making a bacteriological diagnosis of whooping cough before a clinical diagnosis can be made. As a means of controlling the spread of the disease, however, this will be of relatively little value since even the earliest cough plate diagnosis will be made after the individual will have passed his period of greatest infectivity. There is at present no evidence that cough plates have any special public health significance in other directions than early diagnosis.

STANDARDIZATION OF THE COMPLEMENT-FIXATION TEST FOR SYPHILIS*

RUTH GILBERT, M.D., F.A.P.H.A. (*Life Member*)

Division of Laboratories and Research, New York State Department of Health, Albany, N. Y.

PERSONAL preference for particular details in the complement-fixation test for syphilis renders improbable the general adoption, at this time, of any one technic *in toto*. If agreement on basic principles can be secured, however, a nucleus for a standard method will be provided. Coöperative studies made prior to 1930 indicated that, even with manifold variations in details, the complement-fixation tests for syphilis extensively used in Canada and the United States had much in common; also, that the least satisfactory of them, although generally lacking in sensitivity, seldom gave definite reactions with specimens from persons believed to be free from syphilis. Consequently, the conclusion seems warranted that, if precautions are observed to prevent technical and clerical errors, the chief concern in standardization will be the incorporation of factors found essential for obtaining significant results with weakly reacting sera.

Experience has shown that the outline for a standard procedure proposed

in 1924, when the problem of standardization was first undertaken, meets such a requirement in most particulars. In 1930, this outline was modified to incorporate features of technic believed to be desirable for insuring further the delicacy of the test, and was then submitted to representative serologists, the majority of whom signified hearty accord with the general plan for a standard procedure. The Committee on Standard Methods of the Laboratory Section of the American Public Health Association, at the meeting held in Washington, October 24, 1932, approved the technic recommended as a standard method, and referred the report to the section for final action next year.

Provided the test is performed by a capable personnel and is suitably controlled, and precautions to avoid technical inaccuracies are observed, the outstanding features of the procedure offered as a standard may be summarized as follows: the distribution of standard reagents by central laboratories; the employment of a cholesterolized antigen having a high degree of selectivity with serum from cases of syphilis; the performance of an independent complement-fixation test with a second antigen or of another generally accepted serological test for syphilis (precipitation or flocculation), for

* Abstract of the report of the Referee on the Standardization of the Complement-Fixation Test for Syphilis presented to the Committee on Standard Methods of the Laboratory Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 24, 1932. The complete report will be published in the American Journal of Syphilis.

purposes of control; the use of amboceptor that is markedly hemolytic and practically free from agglutinative properties in the dilutions used; complement that has been proved by preliminary tests to be actively hemolytic and to be readily fixed in the presence of antigen and syphilitic serum and which fails to react appreciably with antigen alone; a comparatively large

amount of patient's serum as well as a smaller quantity to detect so-called prezone reactions; and an extended preliminary period for fixation at a low temperature with an additional exposure for a few minutes at 37° C., or provision for a second test with fixation at 37° C. for from ½ to 1 hour, in case the history indicates the possibility of recent infection.

VITAL STATISTICS

The Census of 1930 and the Growth of Population in Finland During the Last Decade—Some preliminary data concerning the results of the general census of 1930 in Finland are now available. The total registered population of Finland amounted to 3,667,067 persons on December 31, 1930. During the last half century, the population has increased from 2,060,782 in 1880, to the 1930 figure of 3,667,067. The decennial increases during this period have varied considerably. Between 1880 and 1890, the total increase was 319,358, or 15.5 per cent; between 1890 and 1900, 332,422 or 14.0; from 1900 to 1910, the increase amounted to 402,635 persons, or 14.8 per cent; between 1911 and 1920, to 249,610, or 8.0 per cent; and between 1920 and 1930, the increase was 302,260, or 8.2 per cent.

During the decade 1921–1930 the increase in population was slightly higher than during the preceding period of 10 years. In comparison with 1901–1910, however, the increase in population has fallen off very much. When it is considered that the civil war and severe epidemics occurred during 1911–1920, which greatly retarded the growth of the population, the increase in population of the latest period appears very small, for during the years 1921–1930

the conditions were in every respect normal. The mortality was very favorable. The poor growth of population was consequently due entirely to the great falling off in births.

Although the growth of population in Finland during the last 10 years proceeded more slowly than during earlier normal periods it is nevertheless quite large in comparison with conditions in the other countries of Western and Northern Europe. During 1921–1930, the growth of the population for Hungary amounted to 9.0 per cent; for Denmark 8.7 per cent; Belgium 8.2 per cent; France 6.9 per cent; Norway 6.2 per cent; England and Wales 5.3 per cent; Switzerland 5.0 per cent; and Sweden 4.0 per cent.

These figures of population growth are the results of greatly varied conditions of population. Together with Hungary, Finland has the highest rate of natality of these countries, but the surplus of population, for instance in Denmark, is approximately as large in spite of the lower birth rate in this country, because the conditions of mortality in Denmark are more favorable than in Hungary and Finland. In France, immigration from other countries has also contributed toward the increase in population.

Of the total population in Finland in

1930, 1,809,069 were males and 1,857,998 females. The excess of females was 48,929 and there were 1,027 females per 1,000 males. The disproportion between the number of men and women in countries which engaged in the Great War, does not apply to Finland, despite the fact that the latter incurred considerable losses to its male population during the civil war. These losses are not comparable to those suffered by the Great War contestants. As compared with Finland's ratio of 1,027 females per 1,000 males, England showed 1,096, Germany 1,066, and France 1,103 females per 1,000 males.

The rural population still predominates in Finland, although the population of towns regularly grows at a more rapid pace than the population in the country. In 1930 altogether 671,845 persons, or 18.3 per cent, dwelt in the towns and 2,995,222, or 81.7 per cent, in the country. During 1921-1930 the urban population grew by 128,799 persons, or almost one-fourth, and the rural population by 173,461 persons, or only one-sixteenth. The population of the so-called urban districts (boroughs or country-towns) is included in the rural population, though it is really more closely allied to the towns than to the country. Besides there are a number of densely populated districts especially in industrial centers and suburban areas in the vicinity of towns that have townlike settlements. If these are classified in the same category as the towns, the proportion of the population living in towns in 1930 would be 22.1 per cent instead of 18.3 per cent, and the proportion living in actual rural areas 77.9 per cent instead of 81.7 per cent.

The increase in the urban population has in the course of time become more and more dependent on immigration from the countryside. Although the urban population increased almost

fourfold during the 50-year period 1880-1930 the excess of births over deaths, after rising up to 1910, fell off again in absolute figures. During the 10 years 1921-1930 it was about as small as for 1881-1890. Calculated per 1,000 of the average population of the towns, this represents an enormous reduction; from 7.9 per 1,000 in the 1880's to 2.8 per 1,000 for 1921-1930. At the same time the excess of births over deaths in the rural districts dropped from 14.5 to 9.2 per 1,000, also a considerable falling off. The proportion per 1,000 in the rural districts was, nevertheless, during the last decade still more than three times the corresponding figure for the towns.

This reduction in the excess of births was chiefly due to the fall in the birth rate, which was especially marked in the towns. During 1881-1890 the birth rate in the towns averaged 29.2 per 1,000 of the population, whereas in 1921-1930 it was only half that figure of 15.0 per 1,000. With regard to the rural population the corresponding development was as follows: the birth rate was 35.6 per 1,000 in 1881-1890 and 23.6 for the last decade. The reduction is consequently approximately one-third in this case.

During this half-century the death rate also fell off, although to a far smaller extent than the birth rate.

While the difference in the figures of births in the towns during 1881-1890 and 1921-1930 was 14.2 per 1,000, the corresponding difference in deaths was 9.1 per 1,000. In the rural districts the development in this respect proceeded rather more slowly. The difference between the figures for births for these two decades was 12.0 per 1,000, while the figures for deaths recorded a difference of 6.7 per 1,000.—G. Modeen, M.A. *Census of 1930 and the Growth of Population in Finland During the Last Decade*. Bank of Finland. *Month. Bull.* 11:22-25 (Nov.), 1932.

Statistics on Tuberculosis—The 1930 report of the director of the Amsterdam association for the combating of tuberculosis indicates that the regular decline of mortality from tuberculosis in Amsterdam and in the Netherlands as a whole has been continued. The mortality rate of tuberculosis in Amsterdam is lower for men than for women. There have been no changes in the organization of the consultation centers of the district. A characteristic feature of this organization is the coöperation between the association, the physicians, the public health service, and the ministry of labor. As for methods employed, the attempt to search out all patients having open pulmonary tuberculosis has come to the fore. The number of children treated with BCG vaccine increased in 1930, and no harmful effects were observed. The general impression with regard to its value is favorable. The results of the Pirquet reaction on 22,694 children, aged 0-14, for the years 1920-1930 and the year 1930, show that the percentage of positive reactions is diminishing every year.

With reference to urban and rural tuberculosis, Dr. Josephus Jitta has published some interesting figures. The mortality rate in 1930 was only 7.31 per 10,000 inhabitants. During the period 1921-1930, the decline in tuberculosis mortality was 50 per cent for the cities and 33 per cent for the rural districts. The mortality from tuberculosis has increased considerably in children under 1 year of age.—*J.A.M.A.* 100:985 (Mar. 25), 1933.

Industrial States Decline Most in Births—In so far as it has been possible to judge from the partial data available, the decline in the birth rate during the last 10 years has been practically countrywide. Unfortunately, data for only 26 of the 48 states, and for the District of Columbia, are ob-

tainable for both 1931 (the latest year for which the facts have been published) and for 1921; but, without exception, the birth rate has dropped in these 27 areas.

There has been, however, a wide divergence in the rate of decline. The 3 Pacific Coast states, Oregon, with a birth rate of 13.6, California 13.9, and Washington 13.9 had the lowest birth rates in 1931; and Oregon and Washington at the same time rank among the 10 which show the greatest declines in the 10-year period. California just escapes inclusion in this group.

It is most interesting and significant that the greatest declines in the birth rate have occurred in the states of the northeastern section of the country where the population is highly industrialized. Connecticut's birth rate of 15.7 in 1931 shows the very largest drop—one of 34.9 per cent; this being closely followed by the decline of 34.5 per cent in New Jersey which shows a birth rate of 15.6 in 1931. These 2 states stand out in rather bold relief from all the rest; for there is a sizable gap between them and still another industrial state—Massachusetts, with a birth rate of 16.1 in 1931, showing the third largest decrease (one of 31.8 per cent). Rhode Island, with a birth rate of 16.3, had the fifth largest decline; Pennsylvania, with a birth rate of 18.4, had the ninth; and the drop in New York State, with a birth rate of 16.1, was well above the average for these 27 states. Even North Carolina, recording a natality rate of 23.0 and suffering the fourth largest decline, showed a considerable increase in the industrial population during the 10-year period. It seems hardly possible, however, that this alone is sufficient to account for so large a decline as the one of 31.1 per cent observed in North Carolina's birth rate.

In the few Southern and "Border" states included among those for which

there are data for 1921 and 1931, the situation is widely divergent. North Carolina suffered a large decline; so did Virginia with a drop of 29.5 per cent and Maryland with one of 30.0 per cent. In Mississippi on the other hand, the drop was only 11.9 per cent and in the District of Columbia, which is really a city rather than a state, the smallest decline of all (5.9 per cent) was registered.

Among states with largely agricultural populations, Oregon, Washington, New Hampshire, and Virginia were those to suffer above-average drops in the birth rate. Main and Mississippi, on the other hand, suffered the smallest declines; and Wisconsin, Minnesota, Vermont, Nebraska, and Kentucky recorded below-average decreases.

Pronounced differences appear in certain states which adjoin one another and which call for special study. For example, the drop in New Hampshire has been more than twice that in Maine and 50 per cent more than in Vermont. All 3 are states with large rural populations and negligible negro populations. The drop in South Carolina is much less than that in North Carolina, and the decline in Kentucky about one-fourth less than that in Virginia.

New Mexico and Nevada, the states which recorded the highest and the lowest birth rates in the country in 1931, were admitted to the U. S. Birth Registration Area since 1921; and it is thus impossible to determine the extent to which their natality rates have dropped during this 10-year period. New Mexico's 1931 birth rate was 28.4 per 1,000 population and Nevada's 13.2. Both were admitted in 1929, and there was actually a slight increase in the birth rate in New Mexico during the short period of 3 years for which the facts are obtainable. This may well reflect the improvement in birth registration in recent years. In Nevada, the

drop has been small. In Arizona, admitted in 1926, there has been no general downward trend in the birth rate, although a sharp drop was recorded in the year 1931. Arizona, like New Mexico, has a large Mexican population; and it is extremely probable that the Mexicans constitute the one racial element of the population which is not sharing in the declining birth rate. In several of the states, admitted to the birth registration area since 1921, the birth rate showed either a slight upward trend, or no appreciable change until the year 1931. The most conspicuous examples of this are Arkansas (admitted in 1927), Georgia (1928), Idaho (1926), North Dakota (1924), Oklahoma (1928), and Tennessee (1927).

Georgia has the distinction of being the only state to show a higher birth rate in 1931 than in 1930. In Oklahoma (17.7) and Wyoming (19.8), the figures were identical for the 2 years.—*Met. Life Ins. Co. Stat. Bull.* 14:3-5 (Mar.), 1933.

Vital Statistics for Pennsylvania in 1932—The provisional total of live births registered in Pennsylvania in 1932 was 168,202. This number represents a birth rate of 17.1 per 1,000 population which is the lowest ever experienced in the Commonwealth. With the exception of 1929-1930 there has been an annual decrease since 1927 of approximately 10,000 in the number of live births recorded in this state.

Mortality as well as natality was unusually low in 1932. The preliminary general death rate of 10.9 per 1,000 population and the total of 107,595 deaths, exclusive of stillbirths, were lower than any other year's record. When final tabulations for the year are completed, this total and rate will be increased somewhat. And it is likely that the final mortality total for last year will be less than the record low of 1921 when only 109,919 deaths were

reported. Consequently, it is very reasonable to predict that the 1932 general death rate will establish a new minimum.

Compared with preceding years, infant mortality in 1932 was favorable. For the first time in Pennsylvania's history, deaths under 1 year of age numbered less than 10,000. While the totals of 9,919 infant deaths and the rate of 59 per 1,000 live births were provisional, they indicate a final infant mortality figure that is considerably less than average. The death rate from diseases of early infancy of 23.6 per 1,000 live births was somewhat higher than the corresponding rate in 1931 and lower than the 1930 figure.

In four diseases of childhood, namely, infantile paralysis, diphtheria, scarlet fever and whooping cough, the deaths showed increases over 1931. The mortality from poliomyelitis (infantile paralysis) in 1932 was greater than in any year since 1916 when 668 deaths occurred and a case fatality rate of 31 per 100 cases was registered. Last year there were 13 deaths from this disease per 100 reported cases. In spite of a substantial reduction in its morbidity, the diphtheria mortality increased in 1932. However, while this rate of 4.0 per 100,000 population was higher than that of 1931, it was lower

than the diphtheria mortality of any other year.

Judging from preliminary reports, the mortality from tuberculosis and pneumonia in 1932 was lower than in former years. The 1932 death rate from tuberculosis (all forms) was 52.5 per 100,000, as compared with 56.5 in 1931; for pneumonia the 1932 rate was 81.5 and the 1931 rate 97.2. On the other hand, the deaths and death rates from heart disease, cancer, cerebral hemorrhage and diabetes continued to rise, the mortality from these diseases in 1932 being reported as follows: heart disease 238.4; cancer 102.1; cerebral hemorrhage 85.7; and diabetes 25.7. Due to the widespread incidence of influenza in the latter part of the year, there was an increase in the death rate from this disease, from 28.1 in 1931 to 29.3 in 1932. A slight rise was noted in the suicide rate from 4.5 per 100,000 in 1931 to 4.6 in 1932; at the same time there was a slight decrease in the homicide rate from 4.0 in 1931 to 3.9 in 1932. Accident fatalities in general registered decreases from preceding annual reports. This is explained partly by more unemployment and less use of motor vehicles due to current economic conditions.—Pennsylvania Dept. of Health. *Vital Stat. Bull.* 8:6 (Mar.), 1933.

PUBLIC HEALTH ENGINEERING

Protecting Bathing Facilities by Use of an Ammo-Chlorine Boat—The attempt to control the contamination of five bathing areas of the "impounded stream" type and four of the "artificial lake" type scattered over an area of about 200 square miles in the Forest Preserve District of Cook County, Ill., is described.

A portable type of chlorine boat mounted on a two-wheeled automobile trailer was designed. In addition to a chlorinator and ammoniator of the dry feed type, the boat was fitted with racks for carrying at least a thousand pounds of liquid chlorine or ammonia. As great accuracy was not considered essential a control apparatus of the pulsating meter type was used. The motive power was provided by a medium sized outboard motor which also assisted in diffusion of the chlorine.

As local conditions differed in each bathing area an effort was made to adapt the treatment to the particular location. The results are discussed from the standpoint of one location of the "impounded stream" type. The author concludes that it is possible at least temporarily to control the bacterial content of certain natural or semi-natural swimming locations. Chauncey A. Hyatt, *Munic. San.*, III, 9, 370-371. (Sept.), 1932. From *Pub. Health Eng. Abstr.*, XIII (Jan. 7), 1933. Abstr. H. N. Old.

Conformity of Public Water Supplies to the U. S. Treasury Department Standards—The author briefly reviews the evolution of the present Treasury Department Standards for drinking water used on interstate carriers and the procedure followed in the certification of the same. In 1931,

1944 public water supplies in the United States were used as sources of drinking and culinary water by interstate carriers. Seventy-nine per cent of the supplies reported on were recommended for favorable certification, 18.5 per cent for provisional certification and 2.5 per cent prohibited for use. Practically all favorably certified supplies meet the bacteriological standards as did 78 per cent of those provisionally certified. Probably 75 per cent of all public water supplies would meet Treasury Standards as a whole and about 90 per cent would meet the bacteriological standards. R. E. Tarbett, *J. Am. W. W. Assn.*, 24, 9:1281-1287, 1932. From *Pub. Health Eng. Abstr.*, XIII (Jan. 7), 1933. Abstr. H. K. Gidley.

Colon-Aerogenes Types of Bacteria as Criteria of Fecal Pollution—As the result of extensive work of their own and the examination of published articles and reports which they briefly review, the authors conclude: "(1) There is a growing sentiment that the Bact. aerogenes types of organisms in water, apart from Bact. coli, have little significance as criteria of fecal pollution; (2) the fecal significance of organisms designated as Bact. coli and Bact. aerogenes depends on the differential method used to distinguish them; (3) in ferrocyanide citrate agar, the Bact. coli type of colony is the only one strictly characteristic of feces; (4) the Bact. aerogenes type and the intermediate types as determined by this medium, are inconsequential in feces; (5) the distinctive types of colon-aerogenes organisms in ferrocyanide citrate agar retain their definite colony characteristics for at least six

months—as determined by subsequent plating of a large number of strains in the same medium; (6) it is the author's conclusion that the *Bact. coli* type of colony in this medium is alone definitely indicative of fecal pollution; that the *Bact. aerogenes* type and the intermediate types of colonies are of no special fecal significance, and that the latter types should, therefore, be excluded from consideration as evidence of dangerous fecal pollution. F. O. Tonney and R. E. Noble, *J. Am. W. W. Assn.*, 24, 9:1267-1280 (Sept.), 1932. From *Pub. Health Eng. Abstr.*, XIII (Jan. 14), 1933. Abstr. H. K. Gidley.

The Use of Bleaching Clay in Water Purification—"Bleaching clay shows advantage in water treatment by reason of its low price and its great capacity to remove tastes, odors and color. These complex silicates are very inert to reactive chemicals, so that there are not the possibilities of unwanted chemical reactions as there is with superchlorination and with ammonia. Bleaching clay removes unpleasant characteristics from water by removing the substances causing them. Its use does not impart any chemical characteristics to the water that might be disagreeable. To remove unwanted material from water by a natural, untreated substance, as a clay, does not produce any unpleasant psychological reaction in the mind of the consumer. Bleaching clay has the capacity to remove traces of phenol from phenol contaminated water; shows considerable capacity to remove chlorine and sulphuric acid from water containing these chemicals: with aluminum sulphate forms a heavy floc which settles rapidly.

"Bleaching clay itself has bactericidal properties. With prechlorination, the great capacity of the clay to take up chlorine brings about more effective

sterilization and reduces putrefaction and bacterial proliferation in basins and filters to a minimum. The economies possible in lessening the amounts of lime and other chemicals needed reduce the cost of using bleaching clay. Seven to ten cents a million gallons, for a few pounds of bleaching clay used regularly, even when there are no serious color or odor problems, will be well spent as insurance against variability and possible trouble. The more unwanted substances are removed from the water supply, the less chance dissatisfaction will arise." Edw. M. Slocum, *Journal Pennsylvania Water Works Operators' Assn.*, IV, 53-64, 1932. From *Pub. Health Eng. Abstr.*, XIII (Jan. 14), 1933. Abstr. Judson A. Harmon.

Why a Seasonal Quarantine Is Placed Upon Mussels and Clams—Since 1927, when an outbreak of mussel poisoning involving over 100 cases occurred in and around San Francisco, the California State Board of Health has established a quarantine on shellfish during that season of the year when the poison is at a maximum in the mussels and clams. The toxicity of the shellfish varies from season to season and from month to month, increasing during the summer months, and it may reach a maximum as early as June or as late as September. It has been found that $\frac{1}{4}$ ounce of bicarbonate of soda added during cooking, for each quart of water used, destroys 85 per cent of the poison when the cooking process is continued for 20 to 30 minutes.

Occurrence of the poison in clams does not run strictly parallel to its occurrence in mussels. In both cases the poison is confined almost entirely to the intestines of the bivalve and since these organs are larger in clams they are generally discarded, hence clam poisoning is not as frequent as mussel poisoning. It is to be remembered that cooking alone, without the

use of bicarbonate of soda, does not reduce the danger of poisoning. By general use of the bicarbonate of soda and by laboratory tests on the strength of the poison, it may be possible in the future to reduce the time of quarantine to a minimum. H. Muller, *Weekly Bull. Calif. State Dept. of Pub. Health*, XI, 35:138-140 (Oct. 1), 1932. From *Pub. Health Eng. Abstr.*, Vol. XIII, Jan. 21, 1933. Abstr. Frank E. DeMartini.

New Paris—A very serious view is taken of the inadequate supply of potable water and means of sewage treatment for the rapidly growing population of Paris. At present about 3 mil. c.m. of water is provided, 1,815,000 c.m. of which is purified Seine and Marne water. It has been estimated that by 1960 a further 2 mil. c.m. will be required, which for navigation reasons cannot be withdrawn from the river. In 10 years the quantity of water used for condensation purposes in big electrical power stations will have risen to 120 c.m. per sec. from 12 c.m. per sec. A corresponding increase in the temperature of river water will give rise to fogs in the valley. Ninety-two mil. c.m. of sewage is discharged untreated into the Seine; consequently river water must be treated with high chlorine dosages. It is urged that increased treatment of sewage on land, and the construction of impounding reservoirs for potable water should be immediately undertaken if a crisis in 10 years' time is to be averted. F. Bordas and J. Riviere, *Rev. d'Hyg.*, 8, 38, 1930. From *Summary of Current Lit.*, Water Pollution Res., VI, 3:77 (Mar.), 1933.

The Water Supply and Sanitation of Paris and District—The writer, in a critique of "New Paris" by Bordas, F., and Riviere, J. (see previous Abst.) considers that the situation in the water

supply and sanitation of greater Paris is not as grave as they assume. He ascribes the defects of the water supply system to an out-of-date administrative organization. The water supply of Paris itself is sufficient and more for present day needs, but a 5 per cent increase per annum in the potable water demand is foreseen in the next 20 or 30 years. The suburbs generally have an insufficient water supply, e.g. in the Seine Department only 150 litres per head of potable water is provided, while in Paris there are 500 litres per head. A greater coöperation between Paris and its suburbs and the lessening of the number of separate water works is urged. New sources of potable water for greater Paris are under consideration and will probably be provided by ground water from the Loire valley. The program of the Ministry of Public Works to erect a system of dams in the upper Seine basin which will regulate the water level at the mouth of the river for navigation purposes, and have an accessory value in controlling flood levels, producing electrical energy, and providing a supplementary supply of water for Paris is described. In discussing the sewerage of Paris the writer describes briefly the program put forward in 1929 by the Conseil-general of the Seine which includes the construction of a chain of collecting sewers encircling Paris to the north and south and avoiding discharge of sewage into the Seine or Marne during their flow through the city. An artificial treatment plant capable of enlargement according to future needs is also to be erected to prevent pollution of the Seine, and the present irrigation fields are to be maintained. The difficulties involved by this scheme, including coöperation between the neighboring departments, are discussed. The author shows that the raising of the temperature of the river by the condensation waters from the power sta-

tions is not at present a serious problem; should it become so in the future the improved sanitation conditions will counteract its effect. H. Giraud, *Ann. d'Hyg.*, 9, 293, 1931. From *Summary of Current Lit.*, Water Poll. Res., VI, 3:77-78 (Mar.), 1933.

Cotton Guard Rope in Swimming Pools as Source of Colon-Aerogenes Group—Positive presumptive tests which gave typical aerogenes colonies on partial confirmation were given by water from a swimming pool after the introduction of a cotton guard rope which was immersed in the water. Examination of strands from the rope showed the presence of the colon-aerogenes group and it was found that bacterial growth was possible upon the moist rope. Guard ropes of organic material are unsuitable for use in swimming pools. H. W. Leahy, *J. Am. W. W. Assn.*, 24, 1062, 1932. From *Summary of Current Lit.*, Water Poll. Res., VI, 3:87 (Mar.), 1933.

A New Nutrient Medium for the Isolation of B. Coli—A new medium for the detection and isolation of B.

coli utilizes the characteristic growth of B. coli on agar containing traces of copper. Two drops of 10 per cent copper sulphate solution are added to 10 c.c. alkaline liquid agar; the mixture is autoclaved at 110° C. for 20 mins. and then poured into petri dishes and left to set. Colonies of B. coli develop rapidly. Each has a fine rim and is raised at the center; a central yellowish brown zone is surrounded by a yellow and then a light yellow zone. All of these, especially the middle zone, show a copper lustre. The usual cultural and fermenting properties of the colonies are maintained. Selectivity is exhibited by the medium; typhoid, paratyphoid, Gartner, and dysentery, diphtheria bacilli, fecalis alkaligenes and lactis aerogenes bacteria and staphylococci do develop in it after 24 hours incubation at 37° C. Very rarely whitish, not transparent colonies of B. paratyphosus B. may appear. The imperfect development of the typhoid bacilli may be used as a criterion for their identification. G. Cascelli, *Zbl. für Bakt.*, I, Orig., 124, 537, 1932. *Summary of Current Lit.*, Water Poll. Res., VI, 3:94 (Mar.), 1933.

INDUSTRIAL HYGIENE

Lead Poisoning, New York State, 1931—There is given a table of 85 cases of lead poisoning reported during 1931—27 cases among general painters, 24 among storage battery workers, 6 among color manufacturers, 5 among printers, and the balance scattered. A conspicuous reduction was noted in lead poisoning in the storage battery industry, largely due to the efforts of one large plant to control it.—Adelaide Ross Smith. *Indust. Bull.*, New York Dept. of Labor, 11, 10:315 (July), 1932. E. R. H.

Silicosis—The Hazard, What It Is, and How It May Be Prevented—This is a summary of the present-day problem of silicosis, particularly as related to New York State and should be read in the original by those further interested: Two or three important features stand out in the prevention, such as physical examinations and the control of silica dust in the breathing atmosphere.—J. D. Hackett, *Indust. Bull.*, New York Dept. of Labor, 11, 15:475-476 (Dec.), 1932. E. R. H.

Silicosis in Great Britain—The Secretary for Mines was asked by Mr. David Grenfell the number of cases of silicosis reported from each of the British coalfields, to which he replied that silicosis was not a notifiable disease and the only figures were those of cases paid compensation. The number of such cases between February 1, 1929, and December 31, 1931, was 91, including 20 fatal cases. The number of cases in 1931 in which compensation was paid was 52, of which 13 were fatal.

The Coal Mines Act requires the

prevention of dust from power drills when they are used for drilling in ganister, hard sandstone, or other highly siliceous rock.

The stone dusting of colliery roadways as a protection against coal dust explosions has been generally enforced for nearly 12 years and has proved remarkably effective. The Secretary knew of no evidence that the practice had been injurious to health. The evidence in the very few cases (of silicosis), which were not definitely associated with the use of power drills in siliceous rock, was not conclusive. The condition of the lungs known as Anthracosis was not specifically related to the use of power drills.—Parliamentary Debate, House of Commons, Nov. 15, 1932, *Indust. & Labour Inf.*, Dec. 12, 1932, p. 330. E. R. H.

Occupational Disease, New York State, 1932—Typed tables show the prevalence and nature of occupational diseases reported, divided into those "up-state" and those for New York City—the latter further subdivided into those which were allowed compensation and those which were disallowed.

The grand total for the year 1932 was 610, of which 458 appeared on the compensation schedule and 152 were unclassified. The largest single group was benzol, etc., with 107 cases, followed by dermatitis due to alkalis, 102 cases; lead poisoning, 79 cases; and dermatitis due to oils, 61 cases; while afflictions due to lacquers, solvents, carbon monoxide, petroleum products, and chrome were all fairly frequent.

A more extensive table compares the years 1930, 1931, and 1932, and arranges the causes in alphabetical order

—the occupational diseases reported being due to about 140 causes. The totals for the 3 years were 864, 568, and 615 respectively. The prominent causes, in addition to those mentioned above, were: Acids, anilin dyes, amido-derivatives of benzine, anthrax, arsenic, benzine, calcium hydroxide, cement, various forms of dermatitis, dyes, dusts, mercury, poison ivy, silica, soap and soap powders, sodium hydroxide and turpentine.—Division of Industrial Hygiene, New York State Dept. of Labor (received March, 1933).

E. R. H.

The Position of the Medical Officer of Health in Relation to Industrial Hygiene—After reviewing the historical fact that industrial hygiene in the British Isles has been administered from a central source—in more recent years by the Home Office—the author discusses the experiences in the city of Coventry following a voluntary liaison set-up between the Engineering Employers' Association and the Local Board of Health of which the author is Medical Officer. Thus the Local Board fills an advisory rôle in relation to factory welfare and occupational hygiene in a vicinity employing some 50,000 persons, and factory hygiene is not omitted from the local public health scheme.

In the discussion which followed, Dr. Clyde McKenzie (Smethwick) opposed the control of factory inspection by the local authority for several reasons: The loss of time in a factory was almost entirely dependent on the general health of the workers rather than on occupational risk (in which situation the local medical officer of health already had ample powers), and a small centralized staff was necessary to build up the special knowledge necessary to understand and control occupational diseases. Local interest was acceptable from the voluntary

standpoint, but any legislative control should be from a central office to insure uniform standards.—A. Massey, *J. Roy. San. Inst.*, 53, 9:494-499 (Mar.), 1933.

E. R. H.

Frequency of Pneumonia Among Iron and Steel Workers—This *Bulletin*, after describing the statement of the problem, takes up the factors apart from working conditions such as seasonal influences, economic status, age, race, alcoholism, and community pneumonia, followed by a study of the incidence of pneumonia in relation to the nature of iron and steel working conditions.

Previous studies of industrial sick benefit associations by the Public Health Service have consistently shown a higher rate of pneumonia among these employees than those in other industries as a whole. The present study, 1924-1928, showed 35 per cent increased incidence of pneumonia above the average for all reporting establishments in the steel industry. The highest rates were among employees of the blast furnace, coke plant, open hearth, general labor about the mills, and rod and iron mills. The departments showing a high pneumonia rate tended also to show abnormally higher rates of influenza and other diseases of respiration.

Factors apart from working conditions were of insufficient influence to account for the excesses described. The frequency of pneumonia among men exposed to inclement weather was 13.6 cases annually per 1,000. The rate among men subjected to heat hazards involving wide temperature changes was 12.6 per 1,000. That among 1,000 factory men exposed to no industrial condition was only 3.9 per 1,000. Strenuous work also appeared to intensify the hazard when performed under intermittent exposures to high temperatures. There appeared to be no way

of evaluating the effect of dust upon the incidence rate of pneumonia. Likewise, the influence of gases alone could not be measured, although the only gas found in sufficient concentration to produce physiological changes was sulphur dioxide. A common factor appeared to be, sudden cooling or chilling of the body.

Of those who died of pneumonia, nearly one-fifth succumbed before the end of the first week of illness, while among those who recovered, 50 per cent were disabled for 6 weeks or more. These tended to show a higher rate of heart effects than found in a control group in the same plant or among industrial workers in general. A number of recommendations complete the report.—Dean K. Brundage *et al.*, *Bull.* 202, U. S. P. H. S., Nov., 1932, 51 pp.
E. R. H.

Annual Report, Institute for Science of Labour, 1930-1931 (Japan)—This report of 25 pages embodies the findings of a group of research workers and investigators devoting their time to various subjects in occupational hygiene and diseases.

The organization of the Institute is described and the first 10 years of its progress completed July, 1931. The report gives a list of the lectures and reports made by the members of the staff at various meetings and congresses as well as abstracts of the papers published by the staff for the fiscal year ending July 30, 1931. Most of these papers (34 in number) have appeared in the *Journal of the Science of Labour*, but a number of them are cited in the *Japanese Yearbook of Social Science* and some in the Commemoration Number of the 10th Anniversary of the Institute. It also has been decided to select and translate some of the papers into English and German, and a list of a dozen of these is advertised. The report also contains a diagram of the

ground plan of the Institute and a list of the staff of some 30 persons.—Gito Teruoka, Director, Institute for Science of Labour, Kurasiki, Japan (received October, 1932).
E. R. H.

Occupational Diseases in Czechoslovakia—Cases of occupational diseases notified to the Accident Insurance Institutes at Prague and Brno between July 1, 1932, and November 30, 1932, were as follows: Prague, 595; Brno, 302. Most of these were cases of silicosis; cataract, lead poisoning and cancer come next on the list. The Czechoslovak Act relating to compensation for occupational diseases came into effect July 1, 1932.—*Indust. & Labour Inf.*, XLV, 11:322 (Mar. 13), 1933.
E. R. H.

Sickness Among Male Industrial Employees During the Final Quarter of 1932—The influenza epidemic during the fourth quarter of 1932 caused a higher rate of sickness among employees in the selected industries studied, but if this cause is deducted the frequency of sickness is just about the same as in the corresponding quarters of 1930 and 1931.—Dean K. Brundage, *Pub. Health Rep.*, 48, 13:322 (Mar. 31), 1933.
E. R. H.

Pottery—The report includes a descriptive introduction, the extent and scope of the pottery industry in the United States and the conditions found in three typical plants, after which the process of manufacture and the potential health hazards are given. These latter are discussed under the heads of dust, heat, lead poisoning, chemicals, dampness, other hazards, and "frequency and severity rates." In addition, there is a Classification and Index of Jobs with the chief hazards given for each.—Retail Credit Company (Atlanta, Ga.), *Industry Report*, 8, 4:33-42 (Apr.), 1933.
E. R. H.

FOOD AND NUTRITION

Vitamin D and the Conservation of Calcium in the Adult. *II. The Effect of Vitamin D on Calcium Conservation in Adult Rats Maintained on Low Calcium Diets*—In a previous paper (*J. Biol. Chem.* 97:265, 1932), results were reported on feeding a high calcium-low phosphorus rachitogenic ration with and without additional vitamin D.

In the present paper are reported results obtained on adult rats kept on a ration low in calcium and phosphorus with and without vitamin D supplements.

Three rations were used in these experiments, one consisting of yellow corn, wheat gluten and sodium chloride, and containing 0.058 per cent calcium and 0.28 per cent phosphorus.

The second was a duplication of the first ration except that vitamin D had been synthesized therein by exposure to ultra-violet radiations.

The third which served as a normal control ration, was composed of two-third stock Ration 14 (*Science*, 57, 449, 1923) and one-third whole milk powder. It contained 0.56 per cent calcium and 0.58 per cent phosphorus. Four groups of female rats were used. One group was killed at the beginning of the experiment and the other three received the rations.

The general appearance and behavior of the rats showed no significant variation from the normal until the 10th week, at which time they became so restless it was necessary to transfer them to individual cages. By the end of the 15th week the differences in the three groups were very pronounced. On the non-irradiated low calcium ration diet there was a hypertonic condition of the muscles and the animals

were emaciated and senile in appearance. The rats on the irradiated low calcium diet did not become so emaciated and there was no muscular tenseness.

The femurs suffered a 10 per cent reduction in ash. The introduction of small amounts of vitamin D into the calcium-deficient ration provided considerable protection from mineral losses in a parallel series of the rats. Only about 6.5 per cent of ash was lost from the femurs. Weight losses were greatly reduced. Calcium content of the blood serum was increased and the parathyroids were maintained almost normal in size.

III. The Effect of Vitamin D on the Teeth of Rats—These experiments were carried out in two series. For the lactation series the stock diet consisted of yellow corn, oil meal, crude casein, alfalfa, bone ash, sodium chloride, dried yeast, skim milk powder, and butter fat. Vitamin D was added in the form of irradiated dried yeast at a level of 0.5 per cent of the weight of the ration.

In the low calcium series the diet consisted of yellow corn, wheat gluten, and sodium chloride. Vitamin D was synthesized in the ration by treating it with ultra-violet radiations. A stock rat ration which was unable to maintain normal ash content of bone in female rats during lactation did not lead to depletion of minerals in the incisor teeth, and liberal additions of vitamin D correspondingly had no effect on the teeth.

However, a ration low in calcium when fed to adults over a long period of time was unable to maintain normal composition of teeth or bone even without the strain of reproduction. The sole addition of vitamin D resulted in

almost complete protection against mineral losses, as revealed by analysis for ash and histological examination. For complete protection the ration was probably too low in calcium.—Vera M. Templin and H. Steenbock, *J. Biol. Chem.* 100:209 (Mar.), 1933.

Antimony Poisoning Due to the Use of Enamelled Vessels—In recent years there have been several outbreaks in England of antimony poisoning due to the use of enamelled vessels of inferior quality for the preparation of acid drinks such as lemonade. The first of these outbreaks occurred in the summer of 1928. Lemonade was prepared in a number of new white enamelled buckets and allowed to stand over night. Next morning they were placed in various parts of a building for employees of a local firm.

By noon, 70 of 500 employees had been served, and practically all were speedily sick. Fifty-six of the patients had to be removed in an ambulance. The symptoms were a burning sensation in the stomach, colicky pains, nausea, vomiting, and collapse. In no case did the vomiting amount to hematemesis, and intestinal symptoms were absent. The period and degree of distress varied with the quantity of drink consumed, and in many of the younger girls signs of hysteria were present in addition to the symptoms of poisoning. In most cases the patients were able to return to work within three hours, only two being detained in the hospital over night.

The "lemonade" crystals which were used to make the lemonade were examined and found to contain 80 per cent of sugar, 18 per cent of tartaric acid and $1\frac{1}{2}$ per cent of carbonate of soda. The enamel on the pails contained about 3 per cent of antimony oxide. The tartaric acid had dissolved the enamel and presumably formed tartar emetic with the antimony pres-

ent. A tumblerful of the liquid was found to contain $1\frac{1}{2}$ grains calculated as tartar emetic, the emetic dose being $\frac{1}{2}$ to 1 grain.

The second outbreak occurred in 1929 at a gathering at which 120 persons were present. The lemonade in this case was made from sliced fresh lemons, and was prepared in white enamelled iron jugs. Twenty-five to 30 persons were ill within half an hour after consuming the drink. The enamel of the jugs was found to contain 9 per cent of antimony oxide.

The third outbreak occurred in 1932 in a large London hospital. Sixty-five of 70 persons present were seized with acute symptoms of vomiting. In this case also the lemonade was prepared from fresh fruit in white enamelled iron jugs.

A warning is sounded against the use of low-grade enamels. These are made from a mixture relatively low in silica content and are fired at a low temperature. They are not acid-proof, and seem to be readily dissolved by citric, tartaric, acetic, and other acids present in foods. The buckets and cans responsible in the above cases were not intended for use with food or drinks, but were so used and there was nothing in their appearance to suggest that they were not suitable. The public should, therefore, be warned that enamelled hollow-ware vessels intended for other purposes may be dangerous if used for the preparation or storage of food or drink.—Ministry of Health, *Brit. Food J.*, 35:24 Mar.), 1933.

Relation of Vitamin A to Cancer—Kuh reports that the study of the effect of varying dosages of vitamin A from various sources on the growth of tumors of mice under controlled conditions showed that the tumor implants of mice were not affected by those amounts of vitamin A contained in the usual diet, supplemented by as much as

500 units of vitamin A. On the other hand, when maximal dosages (1,000 or more vitamin A units) of the provitamin carotene were administered, varying degrees of inhibition of tumor growth were observed.

The utilization of the carotene was limited by a number of factors, including apparent failure on the part of the animal to convert the carotene to vitamin A, this incompetence being due to the absence from its liver of the enzyme carotenase. The problem of inhibiting tumor growth by means of vitamin A becomes one of determining whether more efficient methods of administration can be devised. Two possible procedures are worthy of trial: (1) the feeding of carotene plus the injection of a source of enzyme carotenase, and (2) the feeding of new preparations of vitamin A concentrate.

The administration of the maximal dosages of vitamin A appeared to be without a harmful effect on the animals. This suggests that the inhibited growth of the tumor is the result of a specific action of the vitamin A on the cancer cell.—*Yale J. Biol. & Med.*, 5:123, Dec., 1932 (Abstr. *J.A.M.A.* 100:779, Mar. 11, 1933).

The Antiscorbutic Value of Fresh Lime Juice—A scurvy producing diet of caseinogen, calcium carbonate, sodium chloride, oats and bran was given *ad libitum*. This was supplemented with 5 c.c. cod liver oil daily per animal. Young guinea pigs usually weighing 300–400 g. were used. The juice was prepared fresh daily from ripe Egyptian limes not more than 2 days gathered and was given in daily doses of from 0.5 c.c. to 3.5 c.c. It was found that the minimum protective dose of fresh lime juice is 1.5 c.c. and partial protection is conferred even by the smallest dose given, 0.5 c.c.

Comparisons were made between the Egyptian and West Indian limes since

the latter had been employed in previous experiments reported. Ripe fruits were used but the juice was kept in a refrigerator throughout the experiment which was approximately 2 months. It was shown that in both juices the antiscorbutic principle is not stable for a long time. During the experimental period deterioration was such that 3 c.c. failed to protect against the diseases. There seems to be no doubt that loss of this factor takes place at a much greater rate from lime juice than from lemon juice. Previous investigators (*Biochem. J.* 15:83, 1921), obtained slightly better results with green than with ripe limes, thus indicating that loss of the antiscorbutic principle commences with the process of ripening.—Ali Hassan and Rizk Basili, *Biochem. J.* 26:1846, 1932.

Vitamin C and the Suprarenal Cortex. I. Antiscorbutic Activity of Ox Suprarenal—Supplies of fresh ox suprarenal were obtained daily or every second day from local slaughterhouses. In order to avoid possibility of adrenalin poisoning, only the cortex was fed. The antiscorbutic activity was determined by curative tests, and by the microscopic tooth structure method.

In the first test, male guinea pigs, weighing 250 g. were placed for a preliminary period of 10 days on a scorbutic diet of bran, oats, egg-yolk, salt and cod liver oil, alone, and then supplemented by 15 g. of cabbage. Graded doses (0.25, 0.5, 1.0 and 2 g.) of suprarenal cortex were fed and recovery rate noted. Graded doses (.75, 1.5, 3 and 6 c.c.) were fed at the same time to another test of animals. It was found that 2.0 g. of raw suprarenal cortex corresponded very accurately with 6 c.c. of orange juice, 1 g. with 3 c.c. and 0.5 g. with 1.5 c.c.

In the second experiment, young guinea pigs weighing about 300 g. were

given the basal diet with doses of suprarenal cortex at levels of 0.5, 1.0 and 2.0 g. To another set of animals orange juice was fed at levels of 1.5, 3 and 6 c.c. After 14 days the animals were killed and cross-sections of the roots of the incisors were prepared by the usual method.

Raw suprarenal cortex (ox) was found to be a more powerful anti-scorbutic than any natural source known and possesses three times the activity of orange juice. The degree of activity corresponds with the value predicted on the basis of the relative yields of hexuronic acid obtainable from the two sources. It is concluded that vitamin C is either identical with hexuronic acid or is a substance possessing a close similarity to it.

Preliminary results show that in guinea pigs the vitamin C activity of the suprarenal is lost with the onset of scurvy. It is supposed that vitamin C plays a special rôle in the physiology of the suprarenals.—Leslie Julius Harris and Surendra Nath Ray, *Biochem. J.* 26:2067, 1932.

Vitamin A Content of Naturally Colored Nut Margarines—This experiment was carried out to determine the vitamin A content of a number of nut margarines colored by the addition of palm oil. Male albino rats, 28 days of age, and averaging about 59 gm. in weight, were used. These were fed the

"colony diet" recommended by the vitamin assay committee of the American Drug Manufacturers' Association. When the body was depleted of vitamin A, which required about 4 weeks, different levels of nut margarines were added to the basal diet, and the experiment continued 8 weeks or until death.

Sufficient vitamin-free cottonseed oil was fed to each animal to make the total fat constituent of the diet one gram per day. To the diet of the animals which were used as controls were added different daily levels of butter. Records of the growth of the animals are given and it was thought some of the growth might be due to the vitamin A in the added milk. Some of the fat from each sample was freed from the salt, water, and curd.

An amount equivalent to the level required to produce an average gain of 3 grams per week was fed to a second series of rats. The average growth curves for these animals were practically identical with those of the animals receiving equivalent amounts of the original sample; this indicated that the vitamin A content was derived from the fat rather than from the added milk. From the results of this experiment it is concluded that palm oil shows promise as a source of growth-promoting substances in nut margarines.—Charles F. Poe and Hazel A. Fehlmann, *J. Indust. & Eng. Chem.* 25:402 (Apr.), 1933.

CHILD HYGIENE

SCHOOL HEALTH PROGRAM FOR THE VIRGIN ISLANDS OF THE UNITED STATES*

SALLY LUCAS JEAN, F.A.P.H.A. (*Life Member*)
New York, N. Y.

UNDER the able administration of Governor Paul M. Pearson, an efficient health department has been developed in the Virgin Islands. Dr. R. B. Stafford, the Director of Health, a member of the American Public Health Association, had had many years of experience in health department activities in this country before going to the Islands.

The population of about 22,000 is more than 80 per cent negro; the white group being chiefly of Dutch, English, Danish, or French origin. English is the language generally spoken. Twelve thousand of these people live on the island of St. Croix, while 500 are on St. John, and the remainder on St. Thomas from where governmental affairs are carried on.

Hospitals were established under the Danish administration before the United States purchased the Islands from them in 1917, and since then have been well administered by our navy, as well as by the civil government appointed in 1931. American and European trained doctors are in charge of the hospitals, each of which has established training schools where native girls furnish service under American graduate nurses. A leper hospital with about 80 inmates is under

the able direction of Dr. James I. Knott who serves not only as the director of health for one of the general hospitals, but is in charge of certain local public health activities.

It is thought that the brilliant sunshine probably accounts somewhat for the low record of communicable diseases prevalent, but the availability of medical, surgical, dental, and nursing services with organized welfare activities and a highly developed public health department, tells its own story. Few places in the world furnish as adequate health services as are available to the people of the Virgin Islands.

The school population of 4,000 have a health and dental examination yearly, and free dental as well as surgical and medical service are obtainable by them all. Elementary, junior, and senior high schools are well established and little pressure is required to secure regular attendance as the people desire education for their children. The teaching staff are largely native, supervised by white men and women trained in the United States. The educational standard for teachers is rapidly rising under the progressive and sane leadership of George Ivens, Director of Education.

To ascertain how the school children lived, many homes were visited with Miss Lucy Gillette, the Commissioner of Welfare, who has faithfully and wisely served the people for many years as a public health nurse under the

* At the request of Governor Paul Pearson, the writer spent some weeks during January and February in the Virgin Islands assisting the health and educational authorities in the development of their school health program.

American Red Cross before being appointed in 1931 to her present post. Much time was spent in schoolrooms and in talking with teachers, as well as in conferences with educational and health officials. It was evident that many necessary factors of a school health program existed; indeed, more than are usually found in school systems of our highly organized states, but it was possible to suggest ways and means by which these could be coördinated and so serve more fully the needs of the children. Practical steps were also indicated for the improvement of school health environment and teaching.

The receptive attitude of the authorities leads me to believe that we may, at some not too distant day, find an ideal school health program functioning in these schools.

Though economic conditions are not good, the people seem very well nourished. Rice, fish, bananas, and sugar cane are their chief diet, but this is now being enriched due to the

encouragement which the government is offering whereby the people can grow and consume more vegetables. Fresh water is scarce because of the coral formation of the Islands, and the rain water is carefully husbanded in cisterns, but lack of water does not prevent the people appearing clean as to body and clothes. The sea is available to all and a definite effort is being made to encourage bathing in the sea regularly.

The beautiful bodily carriage noticeable on all of the islands can probably be attributed somewhat to the custom of carrying water on their heads, as well as other heavy burdens.

They are dignified people, courteous and polite, and have great pride in the magnificent natural beauty of their islands with deep green tropical growth covering the high hills.

The sapphire and emerald waters breaking on the coral strands made famous in poetry and song, are all here, with quiet, peaceful people proud of their citizenship in the U. S. A.

CHILD HEALTH IN MINING CAMP AND VILLAGE

IN April, 1932, the Save the Children Fund of America requested Dr. Iva M. Miller "to make a survey of the situation as regards children's health in Harlan County, Ky., one of the most populous of the Southern Appalachian coal mining counties, where unemployment has rendered a difficult hygienic and sanitary situation even more difficult. To study the problem of children's health meant that a general survey of the whole community's health and environment should be made." Beginning with reports of the Bureau of the Census and the State Board of Health, and aided by the various physicians in the county and by city and county officials, educators, missionaries, pastors, business men, the State Health Officer and his colleagues, and the

Harlan County Save the Children Fund Committee, with Rev. C. E. Vogel, pastor of the Harlan Church, as Chairman, she proceeded to study Harlan County.

Among the significant facts discovered was this hint of the development of Harlan's coal mining activities, as seen in the growth of the county's population:

| <i>Census</i> | <i>Population</i> |
|---------------|-------------------|
| 1890 | 6,197 |
| 1900 | 9,838 |
| 1910 | 10,566 |
| 1920 | 31,546 |
| 1930 | 64,557 |

The increase of 198 per cent in population between 1910 and 1920 is an index of the amazing—and as we see it now, the appalling—inflation of the coal industry during the World War. Some of the horde of new miners came from outside, but many came

from neighboring mountain counties. During the next 10 years the population more than doubled again, partly due to incoming migration, but also in considerable degree to the high birth rate, which in 1931 was reduced to a few points above that of the state of Kentucky as a whole.

The rapid increase of population greatly complicated the problems of sanitation and health. When a community thus greatly enlarged was stricken by a decline in the prosperity of the coal industry, throwing thousands of men out of work, and necessarily making the living conditions of their families worse, the results were disastrous. The preponderance of mine employees in the county is shown by the population distribution in 1930, which is given as, urban 6,596, farm 4,623, and rural non-farm, mostly miners and their families in small camps, 52,968.

In every community, it is possible to obtain a few relevant facts which are indices of the health of the community. Among these is the rate of infant mortality. If this is higher than that of an adjacent community or state, one or more of the several facts may bear part of the responsibility; either the drinking water is unsafe, sewage disposal is unsatisfactory, grade A milk is not available, or the child's food is not being selected, prepared, or administered according to the best ideas of hygiene and sanitation.

The water supply of the city of Harlan was found to be excellent, but that of the rest of the county more or less questionable; mostly wells and springs and, except in a few mining camps, uncontrolled. The county, like many another in the United States, discharges its sewage in the natural streams, all of which are therefore more or less polluted. Two large mining towns have modern plants; but many others are not so happy.

On the positive side the County Medical Society, with 50 members, was found to be a strong influence for health.

The physicians of the county are unusually well trained, and some are especially skilled in surgery. Their monthly meetings are well attended, and the programs presented are of a type which few county societies in America can surpass in quality.

Dr. Miller's report and recommendations—considerably more searching and voluminous than these few hints indi-

cate—seemed to win the full approval of the State Board of Health and the Save the Children Fund.

Realizing that bad health in the majority of cases results not from accident but from negligence or lack of knowledge how to use the means we have for good health, the Save the Children Fund decided to place a Child Health Demonstration in Harlan County, and asked Dr. Miller to serve as its Director. Florence Dunkelberger was engaged as Public Health Nurse, and W. S. Johnson as Sanitary Inspector—both experienced workers in Kentucky.

The work was begun in August, 1932. Outside of the city of Harlan, 8 child health centers for demonstration work were opened—in churches at Evarts, Cumberland, Black Mountain, Benito, Wallins Creek, Alva, Loyall, and Sunshine. Around these centers, committees of local women under Miss Dunkelberger's direction made contact with most of the mothers in the community and took a census of the children under six years of age.

Periodically every 4 to 6 weeks these centers are opened for conferences to examine children and to instruct the mothers. Just prior to the conference, a post card is mailed to each mother, suggesting that she bring Johnny and Mary and Susan and perhaps Ann to the church on the appointed day. And when 50 or 75 mothers show up, with from 1 to 3 or 4 children apiece, it means a busy day for the staff, even when, as in several cases, local physicians have generously aided the Director in giving the health examinations.

Attitudes as well as numbers make conference days difficult. The greatest stumbling block to progress is fear—fear not primarily in the mind of the child, but in the mind of the parent, from whom it is communicated to the child. The babies who have barely reached the point of elementary thinking have imbibed this traditional fear of doctors, and evidently suspect that the examination is going to be some sort of fearful ordeal. The result is that many of them yell, squirm and kick like mule colts, and doctor and nurse get pretty well pommelled before the seance is over.

As an indication of the unfavorable conditions which were found among the first 400 children examined, all of pre-school age, it may be mentioned that

. . . 93 per cent of them needed immunization against smallpox, 90 per cent needed such

protection against diphtheria, 84 per cent needed cod liver oil, 68 per cent were receiving less than their necessary quota of milk, 37 per cent needed treatment for worms, not to mention several other items.

For those requiring cod liver oil—not a medicine for tubercular cases only, but a necessary food for a child from birth until he is 6 years of age, save during the summer when he can take sun baths—we gave to such parents as were unable to purchase it, sample bottles to last until our supply should arrive. A few days ago two tins of 5 gallons each came to Harlan as a gift for use among our neediest. A generous druggist is having it bottled for us and will aid in distributing it among those who can come to Harlan.

The mothers are instructed as to the health care and habits of the children, and those youngsters having physical defects are referred to their family physicians for correction. As soon as all physical corrections are made and the diet and health habits adjusted, so that they have no health liabilities, only health assets, these boys and girls whom we have examined are written off as Blue Ribbon children. They do not come to the conferences again save to be checked up before being reported. In this way we eliminate numbers. When all become Blue Ribboners, our work will be completed—or rather, it would be, save that new births will extend it a while longer.

Now that the mothers are learning the nature of our work, they are responding more heartily to the calls. Some bring boys and girls well along in their teens and beg to have them examined.

One thought on which we are hammering,

and which, if we put it over, will be one of the best effects of our work, is that of the value of the careful, unhurried examination made by the public health doctor when the child is apparently well, in contrast to the panicky, hurried and difficult examination of a child who has shown warning signs of illness for days and perhaps weeks.

Milk is a commodity which cannot be obtained in sufficient quantities in Harlan County. In 1920 the county had no dairies at all. This year there were 24, owning some 500 cows, while 3,500 more cows are privately owned. But still the milk supply is far below what is needed. There are 12,000 children under 6 years of age in the county and 23,000 under 21, that is, still in the growing period. To supply adults with their needed 1 pint a day and each child with 1 quart would require some 50,000 quarts—and the supply is fully 30,000 quarts short of that.

It is therefore planned to introduce milk goats into the mountain regions to supply families where there are small children. It is planned to loan one or more goats to a family until the members are financially able to take them as their own. A good milk goat should produce 1 gallon per day. Goat milk is rich in iron and some salts not found in cow's milk, and the cost of keeping a goat is very little, even in winter. It is hoped that a goat farm may soon be started at one of the settlement schools in the mountains where goats will be bred to supply the needs in several counties.—

Iva M. Miller. *Mountain Life and Work*, Jan., 1933, p. 5.

PUBLIC HEALTH NURSING*

Behavior Aspects of Nursing Education—Behavior is a hard topic to discuss because everybody feels able to express expert opinion on it. We accept data coming from the fields of chemistry, bacteriology, engineering, but we do not like it when the behavioristic sciences of psychology, psychiatry and sociology try to make us see ourselves as we really are. The

reason for this is that for hundreds of years the activities of human beings were ascribed to body, mind, and soul. Clergy and teacher took care of everything above the eyebrows, and activities originating there were called conduct. The doctor took care of everything below the eyebrows. Wundt, a German in the 19th century, first tried to apply scientific methods of approach in a study of human behavior. Now while conduct is a matter about which we pass laws and give advice, behavior is

* Please send printed matter or other material relating to public health nursing to Eva F. MacDougall, 6 State House Annex, Indianapolis, Ind.

a matter which implies only a casual interest in a human being's actions. Yet there must be a wealth of important facts behind various charges in the courts preferred against boys and girls under 16 years of age.

Psychology and psychiatry merge into each other because we are always dealing with varying degrees of abnormality. It is because we recognize in the neurotic, the insane, the feeble-minded and the delinquent so many of our own characteristics, that we feel so free to judge them and prescribe all sorts of advice for their welfare. "As a rule it is far easier to get over a new and unwelcome idea to a factory hand with a mental age of ten years than to put across a similar concept to a person who has practised a profession for years."

Most so-called educated people think gross irrationality is the only symptom of poor mental health, when the mental states that really do the most damage are "mental attitudes of rigidity in thinking, and of impulsive abandonment to emotional undercurrents of jealousy and egotism so often rationalized by the espousal of half-baked theories of omniscience."

Psychiatry has all the characteristics of an overgrown adolescent. The first school of psychiatry damned everybody because of his ancestors. That is now outgrown. The second school was that of focal infection, which thought that all nerves, irritability, tantrums and rage were due to terrible poisons in the large gut, which could be removed by colonic irrigations. The third school is that of endocrinology. We know little about the glands of internal secretion but we talk a great deal about them. The last school is psychoanalysis. All these schools contain important truths, but the danger is for each to regard its trend of thinking the one and only way of life.

Nursing schools in their striving to

be academic must not take over what progressive education is fast discarding. One great teacher-writer speaks of the overestimation of the function of books in the development of intelligence, saying, "A genuinely integrated learning and discipline cannot be attained without an integrated relationship of teacher and pupil."

We accept the principle of individual differences in courses in psychology, physics, and biology, but fail to act upon it in our human relationships. Much medical and nursing energy is expended trying to make fat people lean or lean people fat, when a thousand experts on every phase of growth and development in White House Conference Committees refused even to express an opinion as to what constitutes a state of nutrition. The mental health of an individual depends on his biology and temperament as much as on his intellect, yet education has attempted to standardize its products by evaluating intellectual ability alone.

Interest is increasing in the material taken into nursing schools. Raising educational standards does not entirely solve the problem. Usually the candidate's history and credentials give only an estimate of intellectual performance; personality and make-up are important, also. Personal interviews are perhaps most satisfactory in the right hands. The period of probation needs to be elastic in its expansion of doubtful material.

All Class A nursing schools recognize the necessity for practice and theory in psychiatry. Let the nurses study textbooks in psychology and psychiatry, but who has ever seen texts that deal with the really practical aspects of mental hygiene as they affect everyday living, such as jealousy and self-pity and difficulty in taking criticism, which give us all so much trouble in the management of ourselves and others?

There are matters too, that deal with good taste and manners and plain, common sense, but they are hygienic, nevertheless.

The nursing school curriculum is gradually paying more attention to practice and theory in the field of public health. This phase of preventive medicine has been considered post-graduate material, but because it deals with factors underlying poor physical, mental, and social health, it logically belongs in the undergraduate curriculum. Medical student and pupil nurse need to go with social science into the homes and schools to see conditions of living and education; to see how parents struggle for a livelihood and children get their start.

Social science today is far ahead of public health in its grasp of the problems of human relationships. Public health has doctors and nurses who see only the physical aspects of poor health, and only the problem of relief in social science, while they completely ignore the fundamental principles of social case work, which are so closely related to eugenics, social psychology, and progressive education.

Is it lack of interest, or professional inertia that makes it possible for public health to ignore the preventive side of a branch of poor health whose victims fill more beds in public and private hospitals in this country than all medical and surgical cases together? Although it is ethics for the nurse to go no faster than the doctor in professional vision, yet I believe that the public health nurse has a great chance in her daily work to drive home to public health medicine a larger concept of health than it has today.

A behavioristically intelligent nursing school faculty is just as important as selection of student material and construction of curriculum. Colleges and universities think it is the business of students to look out for themselves so they shy away from personnel departments which industry and big business have found practical. In the

larger nursing schools the educational director can serve as personnel director if she does not have too many students, but she needs to know the individual student nurse from the moment of her entrance to the day of her departure.

Beneath the failures and breakage of the world one invariably finds a long story of poor emotional balance—discrepancy between ambitions and capacities, a floundering with appetites and urges and personal consciousness of inadequacies.

Yes, the greatest value of any educational discipline is the training of the emotional life of an individual.—Esther Loring Richards, *Behavior Aspects of Nursing Education, Bellevue Quarterly*, Mar., 1933.

Miss Wald and Henry Street Settlement Have Birthdays—March 10 marked the 40th anniversary of the founding of Henry Street Settlement and the 66th birthday of its founder, Lillian D. Wald. On this occasion Miss Wald received at her country home in Westport, Conn., telegrams of congratulation from Governor Lehman of New York, and from President and Mrs. Roosevelt.

The first "Nurses' Settlement," later known as Henry Street Settlement, was founded in 1893 by Miss Wald and a coworker, both graduates of the New York Hospital Nursing School. These nurses, in relating their work to the social, economic, and industrial conditions that affected their patients' lives, gave an impetus to the development of visiting nursing. The Henry Street Visiting Nursing Service has served as a model for communities throughout the country. Last year its nurses made approximately 600,000 visits to 100,000 patients in New York.

Miss Wald lives at the Settlement at 265 Henry Street, New York, and is head worker and Head Resident.

The Settlement conducts clubs for boys and girls as well as for mothers and fathers of

the neighborhood; classes in arts and crafts, pottery, dancing, English, citizenship, home-making, first aid; clinics for the mothers and babies, the boys and girls; a music school in which courses are given in all phases of musical study; a theatre and dramatic workshop; social events for the young people; and in the summer time, camps for the boys and girls, a daily play school, and day outings for the mothers and children of the neighborhood.

The administrative headquarters of Henry Street Visiting Nurse Service where Miss Wald maintains an office, is at 99 Park Avenue in a fine building constructed under Miss Wald's leadership and presented to the Service by Mrs. Jacob H. Schiff in memory of her husband. Mr. and Mrs. Schiff were devoted friends of Miss Wald and took active personal interest in the Settlement from its earliest beginnings. Over the fireplace at 99 Park Avenue is this inscription:

This building is given in memory of Jacob Henry Schiff by Theresa, his wife, and is dedicated to the cause of public health nursing, which he long fostered, for love of progressive education, civic righteousness and merciful ministrations.

Nursing training and service as carried on in the hospitals in the '90's were divorced from the families in which their patients came. Miss Wald and her nurses gave nursing a new status by going out into the homes and, by giving hourly service, paid for by the family when possible, brought private nursing within the reach of those with small means or no means at all. The nurses responded to calls from the people themselves and from social agencies, but gave no treatment except under the supervision of a physician. Leaders in the medical profession supported this change of basis in nursing service, but it was fought vigorously by quacks. There has always been a huge field for this service since it has been found that 90 per cent of sickness is cared for in homes.

From the beginning of her nursing career Miss Wald was an insurgent and innovator in the care of the sick, the oldest of woman's functions. She was the first president of the National Organization for Public Health Nursing when it was founded in 1912. She was one of the prime movers in getting a generous endowment which made possible the Nursing Education Department of Teachers College, Columbia University. She brought the idea of school nursing from London in 1902 and offered the services of one of her nursing staff to give a demonstration among school children in New York City. After a month of the demonstration the city made an appropriation for the first public school nurses in the world. Now every English speaking country and many others have adopted school nursing. She made the first suggestions and moves which led to the formation of the Town and Country Nursing Service developed by the American National Red Cross in 1912. She initiated the idea of the Children's Bureau in Washington established by act of Congress in 1912.

It is difficult to measure the contribution Miss Wald has made to social welfare in this country and the world. An editorial entitled "Henry Street" in a New York newspaper referring to her says,

One has but to substitute her name for its English equivalent to make Wordsworth's lines offer suitable tribute to her on this her birthday:

"One impulse from a vernal wood
May teach you more of man
Of moral evil and of good,
Than all the sages can."

EDUCATION AND PUBLICITY*

Motion Picture Memoranda—

Several memoranda of sources for securing pictures, information as to new pictures, and use of pictures. Supplied by Social Work Publicity Council, 130 East 22d St., New York.

"Motion Pictures—Sources for securing by loan, rental or purchase." 2 pp. 3 cents. Not a list of individual pictures or producers, but of free or inexpensive source lists, and new picture information sources. Pictures for entertainment or education in clubs, camps, institutions, etc. Makes accessible the wide field of 16mm pictures.

"Health Motion Pictures." 2 pp. 3 cents. Source lists and national health agencies supplying pictures. Supplementary to memorandum above.

"Amateur Movies." 5 pp. 6 cents. Why, where and how to make useful this exceptionally valuable instrument for the presentation of the health department, the health association, as well as personal and community health. Offers a project for high schools and colleges.

"List of Amateur Movies." 2 pp. 3 cents. Examples of pictures made on health and social work.

To readers of the *Journal* outside of Canada and United States: copies of above memoranda will be sent free without enclosure of postage.

Publicity First Aid for Nursing Groups—The Public Information Kit, designed for publicity chairmen of state, district and alumnae associations, is arranged in a fiber portfolio, compact and easily accessible, and contains a

table of contents, making it easy to put one's hand on the items wanted at the moment. Concrete illustrations of all the points made are listed. The "do's" and don'ts" of good radio speeches are given with mimeographed illustrations of what points a good radio speech should contain, and warnings of the difficulties of getting the "diabolic's" safely through the microphone.

Concrete advice as to physical make-up of a publicity release is given, as well as guidance in the actual content, and suggestions as to photographs and a method of keeping them. There are "fifty-seven varieties of public health nursing news" items listed which can be lifted bodily from the kit, and the locale and names of the board, etc., changed and used in any part of the country. In addition to this digest which can be elaborated on (happily for the publicity secretary who may be in need of ideas) several pages devoted to the preparation of feature articles, show how local color may be added to a news item to make it a good feature.—Stella A. Koenig, Henry Street Nursing Service. American Nurses' Assn., 450 7th Ave., New York. \$1.50. We wonder whether it would not have been better to perforate the various sheets and publications. Some of the users might then have put the contents into a loose-leaf binder. We expect to do this to illustrate the possibility when the Kit is shown at Education and Publicity Headquarters in Indianapolis. *We would like to hear of other such kits offered by national or state groups.*

* Please address questions, samples of printed matter, criticism of anything which appears herein, etc., to Ewart G. Routzahn, 130 East 22d St., New York, N. Y.

Explaining Emergency Diets—The explanation of emergency diets

seems to offer an opportunity for simple dietary instruction. Criticism of emergency dietaries by food faddists and the uninformed may be blunted by careful explanations of the foods allotted or suggested. Why certain items are useful, and others are not, may be stated in strictly non-technical language with a minimum of scientific information.

It seems important to make clear that we are dealing only with emergency conditions. There is danger in such a statement as that "no family needs to be undernourished today even if reduced to the weekly food order provided by the emergency relief funds." This was the lead sentence of a news release widely distributed in one state.

Dieticians and health agencies might well make clear that the adequacy of the relief diet depends upon the community. The specialists are merely helping to make the most of a bad situation.

Some Instruments of Public Information—Do you secure interest through variety in methods? Do you overlook desirable methods in carrying out a particular project? As an aid to affirmative answers to those questions we give a check-list to be cut out or copied for everyday use. Please suggest additions to this list.

1. Newspapers—News (general or departmental), letters to the editor or "Voice of the People," official statements or proclamations, editorials, picture page or rotogravure, feature stories, Saturday or Sunday magazine articles, advertisements.

2. Special local publications—Weekly, monthly or occasional publications issued by religious, club, business, school, or fraternal organizations, or addressed to a neighborhood or other special audience. These are called house organs, bulletins, magazines, news letters, and so on.

Articles in above. Publication of one of your own.

3. Publicity by mail or direct distribution—

Letters, enclosures with letters and packages, annual reports, reports of studies, posters and bulletin board posters, leaflets and folders, booklets and pamphlets, postal cards or post cards, announcements, invitations, etc.

4. Speaking—Talks at clubs, schools, industrial plants, etc., emergency mass meetings, annual meetings, board meetings, anniversary dinners, conferences, classes, invited groups at homes or clubs.

Radio programs.

Possibilities in all the above: Questions and answers, dialogues, plays, etc., etc.

5. Graphic and dramatic methods—Sight-seeing tours or visiting days, exhibits, window displays, contests, talking pictures, silent pictures (including amateur pictures), slides, plays, pageants, parades, demonstrations of methods.

6. Intensive campaigns—Money raising campaign; special educational day, week or month.

7. Personal contact—Personal calls; house-to-house canvass, telephone calls.

"On the Air"—A booklet bearing this title has been issued by the Medical Information Bureau of New York Academy of Medicine, 2 East 103d Street, New York. It seems to be of such practical value that we give it here in full. Copies in booklet form free from Dr. Iago Galdston, above address.

The radio talk stands in a category by itself. The radio speaker is faced with a number of conditions which he does not meet in his other talks. His radio audience is vast but unseen. He can draw no inspiration from the sympathetic eyes of his hearers. The average radio studio even robs one of the companionship of one's own voice, for the room is soundproof, all echoes are deadened, and one's voice sounds muffled.

The radio speaker's audience is mixed. He addresses the young and the old, the rich and the poor, the educated and the illiterate.

These special conditions make necessary a special technic in the composition and delivery of the radio talk.

To begin with, the radio health talk should be written out in full and never delivered from notes or extemporaneously.

Make sure that your manuscript is clearly written and that its pages are arranged in proper order. Before broadcasting, read and re-read your paper. While radio papers must be written out, they should not be read over the radio; they should be spoken. It is

therefore desirable to indicate by signs of one's own composition where special emphasis of tone and voice need be given to what is written. Such signs will help in effective rendition. They act like the markings on a music score.

Be brief in your paper, as a whole, and in sentence and paragraph structure.

Use simple language. Avoid technical and rare terms, or, if obliged to employ them, be sure to define them.

Do not try to cover too much ground in one radio talk. Be content with but one point, if need be, so long as you succeed in making that one point clear.

Summarize your talk at the end—but not in the form of a deliberate summary. Some may have tuned in on the middle of your talk and may wish to know what you said in the beginning:

Be very careful of what you say. Remember that your talk goes into the homes of laymen and is listened to by mixed company. The radio audience is squeamish, touchy, and finicky, and is hemmed in by many taboos. It is readily repelled by detailed descriptions of pathologic conditions and by gory pictures. Many scenes which are commonplace to the medical man are repulsive to the layman. The scientist in his enthusiasm for modern aseptic surgery, will say, "Not even the heart and brain are considered too sacred to be forbidden the exploration of the surgeon's knife." The lay person, when hearing this, is not as much impressed with the marvels of modern aseptic surgery, as he is repelled by the picture of the surgeon's knife exploring the brain or the heart.

Avoid, if you can, in the composition of your papers, direct reference to excreta, to bloody discharges, etc. If you must dwell upon them, use such expressions as will not offend the radio audience.

Avoid time-consuming preliminaries in your speech. Don't tell your audience what a wonderful thing radio is (they know it), or how nervous you are, or how grateful you are to Station XYZ for this marvelous opportunity, etc., etc. Greet your audience and plunge right in.

The informal tone of a conversational style of composition is very effective over the radio. Tell a tale, if you can. The radio audience is more interested in Mr. Jones around the corner who had a little growth on the lip which Dr. Smith advised him to have removed, which was removed in the Henry Street Hospital, and which was found to be a developing cancer, removal of which at an early date is a triumph of surgery, than it is in the plain fact that new growths on one's

lips are dangerous. Of course, all names should be fictitious, especially those of the doctor.

The radio audience is the news-reading public. Hang your tale, if you can, onto some current event with a health slant. Make your talks seasonal, or give a season value to your talks.

The first five sentences of the radio talk should be so written as to bait the listener and compel him to attend to the rest. Select your topics carefully, with a mind to the heterogeneity of your audience. Let your titles be provocative of curiosity and interest.

Speak your paper softly, clearly, slowly. Be especially careful not to swallow your last syllables.

Time your self beforehand, so that you need not hurry your cadence, nor leave the last few paragraphs of your talk unsaid.

You may talk standing or sitting. Most radio talks are better delivered while standing.

Be sure that the announcer has your "topic" properly presented in his introduction. Use only *one* title with your name.

Another Health Education Institute—A second time, so it is planned, a Public Health Education Institute will be held in connection with the Annual Meeting of the A.P.H.A.

Who will attend an Institute at Indianapolis in October? Where will they come from? What kinds of health work are they doing? Such information will help to confirm the idea and aid in the planning. If you would like to attend please drop a postal card to the A.P.H.A. Formal registration will come later.

Teaching of Health—Do you conduct classes, conferences, discussion groups, talks or lectures, or other forms of consecutive presentation of any phase of personal or community health to groups of children, young people or adults?

The Public Health Education Section and this department of the *Journal* would like to hear from health departments or associations, state or local, which carry any of the above in scout

troops, clubs of young people or adults, in a Y.M.C.A. or Y.W.C.A., recreation center, in offices or factories, or elsewhere.

Especially would we like to know of such efforts in reaching those not already organized in groups. Please tell how you find them and get them together in group form for consecutive presentation of personal or community health.

Also, do any other public or private agencies in your state present health in a series of sessions to organized or unorganized groups?

Geography of the Health Education Institute—The following had one or more representatives in the Public Health Education Institute, October, 1933:

Towns and cities, 54; states and provinces, 28; the latter grouped as follows: province, 1; states east and north, 12; D.C., 1; south, 9; west of the Mississippi, 5.

On the list by states the first figure is the number of cities represented; the second is the number of individuals:

Ontario, 2-2; Alabama, 1-1; Arkansas, 1-1; Connecticut, 2-4; D.C., 1-8; Georgia, 2-2; Illinois, 2-8; Indiana, 1-1; Iowa, 1-2; Kentucky, 3-3; Louisiana, 1-1; Maryland, 2-4; Massachusetts, 5-9; Michigan, 4-7; Mississippi, 2-3; New Jersey, 4-4; New York City and Brooklyn, 11; New York State, 7-9; North Carolina, 1-1; North Dakota, 1-1; Ohio, 2-3; Oklahoma, 1-1; Pennsylvania, 5-9; Rhode Island, 1-1; Tennessee, 2-5; Texas, 1-1; West Virginia, 2-3; Wisconsin, 1-1; Virginia, 1-1.

"The County Fair Is Next Week"—"Where can we get an exhibit?" "Send us an idea for our exhibit?" Before long these and similar questions will reach state and national health agencies.

Now is the time to start planning for the county or state fair. And a well planned exhibit is more important this year than ever before.

Will national agencies and state de-

partments and associations now remind their constituents that requests for ideas and information are due several months before the fair dates?

Health Education in Boston—Ruth I. Parsons and C. E. Turner made a study of the school and out of school health education during the school year of 1931-1932, which is reported in *New England Journal of Medicine*, 8 The Fenway, Boston. Jan. 5, Jan. 12, Jan. 19, 1933. 25 cents each issue.

The aims of this survey have been threefold:

1. To determine what agencies are carrying on Health Education in the city.
2. To determine the quantity, quality and adequacy of the work which each is doing.
3. To suggest ways of strengthening the present program of Health Education.

This study was made by the Health Education Research Laboratory of M.I.T. at the request of the Boston Health League. It offers a detailed picture of health education activities by governmental and voluntary agencies, including "organizations whose field is broader than the city of Boston but which contribute directly to health education in the city."

It is recommended "that the Health Education Committee of the Boston Health League should function as a Health Education Council."

A reprint of the three articles from Boston Health League, 43 Tremont St., Boston, Mass. Send 5 cents to cover postage.

MEETING DEPRESSION

"A Half Century's Health Progress," in *Crusader*, Wisconsin Anti-Tuberculosis Assn., Milwaukee. Dec., 1932. Conditions in 1882 and 1932 contrasted. This illustrates one possibility of emphasizing health progress and the importance of present-day health services.

"The School Superintendent and the Health of Children in the De-

pression," by Dr. Thomas D. Wood, Joint Committee on Health Problems. The title might be changed to "The Community and the Health of the School Child in the Depression." National Education Assn., 1201 16th St., Washington, D. C. Samples *free*; low rates for quantities.

Selected mortality figures for 1914 and 1932 appear on cover page of *Health Bulletin*, North Carolina State Board of Health. March, 1933. Part of the editorial application follows:

You want to remember that the better record of 1932 is not an accident. It is the result of persistent, intelligent, scientific efforts. Any lapse in vigilance may mean the return of typhoid fever in every community this or next year. But public health protection, like police and fire protection, costs some money. Are you willing to make the small financial sacrifice necessary for your own safety?

Here are some figures being quoted in New York State: The school district expenditure dollar in New York State, 1931, included the following: health, 1 cent; sanitation, 4.5 cents; recreation, 1 cent; highways, 14.5 cents; education, 37.5 cents. This according to Bureau of Municipal Information, Albany.

A strong plea to halt budget cuts, from *Birmingham's Health*, Birmingham, Ala. Dec., 1932:

In 1932-33: 5 white nurses, to serve distress and educate in health, an area greater than the sovereign State of Rhode Island—two sanitary inspectors, to police a county 50 miles long and 30 wide, and in addition to post quarantine over every case of communicable disease therein—2 food inspectors, to cover every food store, jobber and distributor, every restaurant, every alley hot dog stand in the Fourth City of the South—one quarantine officer to quarantine every case of disease in that city of 300,000, and to do it within an hour or so after its reporting—

But why continue? Citizens of Birmingham are proud of their Department of Health; confident that it is so adequate that never again can pestilence threaten!

More than any other phase of the business cycle, a great depression strains all the facili-

ties of a department of health. More calls for nurses—tremendous increase in the demand for laboratory service—a thousand problems for inspectors—the increasing watchfulness necessary of the unscrupulous anxious to cut corners at the price of the public's health—all these and many other demands arise in a continuous crisis in which the department of health is expected to act promptly and decisively. In grave danger is that city whose health forces meet that crisis with full half their resources gone!

There is an opening now for exhibits in popular teaching. Displays might be worked out to teach wise food buying for the average family, as well as displays showing the reasons for the food combinations recommended for inadequate relief budgets. Also displays showing how to make relief food diets as palatable as possible, are well worth while.

Such displays may be arranged at neighborhood centers of various types. Staff members need give time only to stimulating the idea. The displays may well be carried out by volunteers, with a dietician or home economist as consultant. The possibility of enlisting students in home economics is illustrated by "A Demonstration of Wise Buying," by Heywood and Potter, in *Journal of Home Economics*, Baltimore, Md. March, 1933. 30 cents. The plans outlined could be adapted to other cities. Probably some of the suggestions could be applied to relief diet displays. When such displays are presented to non-relief groups their emergency nature should be emphasized.

"Community Programs for Subsistence Gardens," by J. C. Colcord, is due for publication by Russell Sage Foundation, 130 East 22d St., New York. Intended to guide local relief groups. Deals with "First Steps In Setting Up a Garden Program," "Main Problems of Organization," "Working Conditions and Supervision," etc. It does not deal with strictly horticultural problems.

NEW OR DIFFERENT

National Health Review, Dept. of Pensions and National Health, Ottawa, Ontario. A new quarterly, substituted for former monthly bulletin. A new editorial policy calls for one leading article an issue, news from the provinces, and classified "Abstracts of Current Public Health Literature."

New Mexico Health Officer, Santa Fe, N. M., has changed from monthly to quarterly issues; increased number of pages; added colored paper covers.

Child Health, Oregon Tuberculosis Assn., Portland, Ore., will continue as a bi-monthly.

Eric County Echo, Health Education Service, Buffalo Tuberculosis Assn., 708 Ellicott St., Buffalo, N. Y. "Health Teaching Suggestions for Teachers." Mimeographed. Sample, 3 cents.

Canadian Health, published quarterly by Canadian Social Hygiene Council, 105 Bond St., Toronto. 50 cents a year. "Devoted to the promotion of personal and community health."

The Health Officers' World, International Society of Medical Health Officers, 505 West Cherry St., Milwaukee. Quarterly. \$1.00 a year.

A semi-monthly *News Bulletin*, Ohio State Dept. of Health, Columbus. To supply news copy for use by health commissioners of the state.

News-Week, 1270 7th Ave., New York. More or less like *Time*. To be added to some mailing lists.

TRAINING

A social hygiene study course appearing in *Public Health Nursing*, 450 7th Ave., New York (starting with July, 1932, issue), is available as 8

reprints at 10 cents each. Intended for group discussion or individual study.

A "Study Program in Publicity for Board and Committee Members," appearing in *Public Health Nursing*, starting with Sept., 1932, issue, is available as reprints at 10 cents each. Already issued: "Outline for Analysis of Past Year's Publicity"; "Interpretation: Why, What, Who"; "Newspaper Publicity"; "Feature Stories and Special Column Material"; "Public Speaking"; "Use of the Radio"; "Exhibits." The series will total 9 sections.

Both of the above courses should be useful beyond the nursing field.

DATES AHEAD

May 14, 1933—Mothers' Day. Address: Maternity Center Assn., 1 East 57th St., New York, for plans and materials.

REPORTING

"Investing In Health" is a review of the activities and services of the Welfare Division of Metropolitan Life Insurance Company, New York. Includes 8 diagrams of death rates, 1911-1932. Free.

"Palama's 1932 A Great Year" is Philip S. Platt's annual report for Palama Settlement, Honolulu. It is a 4-page, letter size folder, with display, pictures, "What Our Work Cost," significant statistics, "Extra Dividends" through "varied services rendered the community by Palama staff workers outside the routine of their work," and a first page letter addressed to "the multitude of Palama Settlement's friends who receive this report." By using old cuts, but one, the 5,000 copies cost 4 cents apiece.

BOOKS AND REPORTS

Report of the Water Resources Commission of Maryland to the General Assembly of Maryland.

A report to the General Assembly of Maryland by the Water Resources Commission of that state, setting forth recommendations as to the policy, legislation and methods of financing for the preservation of the water supply resources of the State of Maryland is noteworthy in many respects. The Commission was charged with the duty of

. . . reviewing the underground and surface water resources . . . and of formulating a plan for the preservation, allocation, control and regulation of such water supply resources for the maximum public benefit, safety and use.

The Commission fulfilled its duty. In spite of the very complete, comprehensive mass of related data collected, the summary is reduced to a little more than 1 page and the single recommendation to 1 sentence. However, the brevity of the recommendation does not detract from its importance. This Commission recommends the creation of a permanent water resources commission for the state with general powers to formulate

. . . a water conservation policy, to control the priority, purpose, period, place and quantity of use of water, and to provide for continuity of stream gauging and for the supervision of dams.

One of the most important compilations of information in the report is that showing the water resources control in all of the states. Briefly it summarizes statements of pertinent legislative authority. Maryland is shown to have no body controlling water and water structures and development and conservation. With this knowledge the

suggestion of this Commission has much greater importance. In this day it is of interest to note that because of collaboration between existing state officers, this Commission was able to turn back almost half its appropriation of \$5,000. ARTHUR P. MILLER

Report of the Medical Research Council for the Year 1931-1932—
London: His Majesty's Stationery Office, 1933. Price, 2s net.

This report is full of interesting information on almost every medical subject. The research work of the Council is reported under 7 heads, and being in the nature of a summary, does not lend itself readily to review.

We note with regret the opinion that the common belief that the Manson-Ross discovery had rid the world of malaria has had a bad effect in checking the development of research work. Although 40 years have elapsed, the indication is that there are more cases of malaria today than formerly, and the financial loss due to the disease is incalculable. The world uses approximately £2,500,000 worth of quinine annually, of which more than £450,000 worth is consumed within the British Empire. It is estimated that 47 million cases of malaria could be effectively treated with the amount of quinine purchased in the world. Studies are constantly being made on the new synthetic compounds for the treatment of malaria.

The work on dog distemper has been closed because its object has been achieved. The incidence of distemper among 650 inoculated animals has been only 1.4 per cent, with 0.3 per cent of deaths, against practically 100 per

cent formerly, with a death rate running from 50 to 75 per cent. The money for this work was supplied by the Field Fund, of which some \$75,000 was contributed by the United States.

Maternal mortality continues to be a problem, and excellent steps have been taken to study the disease and bring it under control. Vitamins also continue to attract much attention, as do virus diseases, bacteriophages, etc. Owing to new methods, the tubercle bacillus is yielding its chemical secrets.

Nutrition receives the due amount of study and the relation of dental disease to diet is still under competent investigation. Indeed, as before said, there is scarcely any subject of interest to the medical profession to which reference is not found, and this includes prevention as well as treatment, both medical and surgical.

The grant-in-aid fund by Parliament for the period of the report was £139,000—£9,000 less than for the preceding year.

The report is valuable also on account of the references given, many articles having been already published in various journals.

MAZŸCK P. RAVENEL

100,000,000 Guinea Pigs: Dangers in Everyday Foods, Drugs, and Cosmetics—By Arthur Kallet and F. J. Schlink, *Consumers' Research, Inc.* New York: Vanguard Press, 1932. 312 pp. Price, \$2.00.

Fact and fancy run riot in this "hard-hitting book by two technical experts," as it is called in the blurb on the cover. Much of the hard-hitting seems unfortunately to be below the belt, and the technical qualifications of the writers, who are stated to be engineers, seem to be more pronounced in the art of sensationalism than in the sciences of chemistry, biology, medicine, and public health.

The impression created by this book

is that all fruits and vegetables are dosed with arsenic and lead, and all dried fruits with sulphur dioxide, that all bakery products and meats are bleached or preserved with dangerous chemicals, that most milk comes from tuberculous cattle, that all food and drug manufacturers are mercenary and dishonest, that all advertising agencies are unethical if they are not liars, that the Federal Food and Drug Administration is incompetent, and the law under which it operates is ineffective. This is a conservative statement of some of the immoderate charges with which the book is replete.

Mixed with these many intemperate and exaggerated assertions is some really valuable material on certain arrant quackeries. The chapters on cosmetics, on prescriptions and poison, and on fakes and frauds generally, are sound and sensible, although characteristically rabid. Many of the data are taken from the *Journal of the American Medical Association*, the advertising pages of which are, nevertheless, caustically criticised for their alleged inconsistencies and impurities.

The Federal Food and Drugs Act may be full of defects as the authors declare, but the remedies they so blandly propose are likewise neither practical nor constitutional. Among their weird suggestions is that the enforcement of an improved food and drugs act be transferred to a new Department of Public Health and Education, because "production and financial interests" dominate the present administration and also the Public Health Service.

Such a charge is fatuous, as anyone with the brains of three real guinea pigs who has dealt with these agencies and worked with them will appreciate. The constantly recurring strictures in this book on the motives of the Federal Food and Drug Administration and the innuendoes regarding the efficiency and

honesty of its officials are grossly unfair and unwarranted.

Like much of the material that emanates from Consumers Research, Inc., this book is interesting, entertaining, and somewhat instructive, but extremely unreliable. It represents a vast amount of research, much of which could have been utilized to better advantage. It presents some valuable facts which may help to jar the public out of its customary complacent attitude toward quacks and charlatans, but too many of the data are fantastically exploited and erroneously interpreted. Probably for that reason the book is already more or less of a best seller. Sanitarians may enjoy reading it, provided they do so with an open mind.

JAMES A. TOBEY

Health Stories, Book One—By Anna B. Towse and William S. Gray. Chicago: Scott, Foresman and Co., 1933. 144 pp. Price, \$.60.

What with the mauling teachers are receiving in many quarters, this is, first of all, a cheerful looking book. That is something very important these days. The 97 pictures are the more attractive through the generous use of colors. There are birds, dogs, ducks, and flowers which the children love and pictures also of occasional vegetables which they do not always like so much. Even the child stamping through the rain on page 50 is smiling under his umbrella. These pictures have a lilt about them which is in keeping with the cheerful presentation of the subject matter.

This book is a supplementary reader plus, and is intended for first grade children. It is part of the Curriculum Foundation Series. The 489 words comprising the vocabulary used have been screened in accordance with a yard-stick called the Elson Basic Primer. The authors have tied together specialized vocabulary and specialized

skills, both simple, and both attractive. There is no confusion of ideas, nor has any effort been made to present too many of them at the risk of bulging the child's head. The subject matter used is nicely arranged to fall within reach of the first grader's understanding, appreciation, and practice.

If the present scheme of things demands more work of teachers at less pay, then at least teaching instruments should be kept sharp. The material in this book is so organized as to facilitate its use. There are five units—each one on how to do something; keep clean, care for yourself, grow strong and healthy, keep well, and keep out of danger. Once it is placed in their hands, I suspect many children will request the privilege of taking the book home to show father and mother.

W. W. PETER

The Fine Art of Living—By Daniel S. Sager, M.D. Philadelphia: Dorrance, 1932, 215 pp. Price, \$2.00.

This book is written in simple, popular style for the average lay reader. It treats of the general subject of Personal Hygiene in a simple and elementary manner. Twenty-one of the 35 chapters are devoted to various phases of the nutrition problem including brief mention of vitamins and the place of such foods as eggs, meat, fruit, nuts, cereals, vegetables, sugar, and milk in the diet. Other chapters deal with breathing, bathing, outdoor life, the nature of disease, indigestion, constipation, appendicitis, and long life. Several chapters are one or two pages in length and the average chapter length is about six pages.

The book is without illustrations. It contains no new information for the professional worker. It does not prescribe drugs although it suggests home remedies and hygienic procedures for such conditions as constipation, appendicitis, and overweight. Individuals

would doubtless differ with the author on minor points but the book in general presents commonly accepted facts of hygiene in a simple and readable manner.

C. E. TURNER

Popular Science Talks—Philadelphia College of Pharmacy and Science, 1932. 319 pp. Price, \$1.00.

For several years this Philadelphia institution has collected in one volume the popular science essays given by the college faculty during the preceding season. Although health topics form but a small part of the many fields explored, many of the other subjects are closely related, like physiology and chemistry. The sanitarian will find much of practical value in many and much of interest in all of the dissertations.

Judging from the current number, a library of the complete 8 volumes would give the health worker a readily utilizable source of material for preparations in the many fields of learning in which he is supposed to have ideas. Only a veritable walking encyclopedia of science could pass judgment upon the validity of such a diverse collection of treatises. But one can testify to their readableness and interest.

R. S. PATTERSON

Microscopic Slide Precipitation Tests for the Diagnosis and Exclusion of Syphilis—By B. S. Kline. Baltimore: Williams & Wilkins, 1932. 99 pp. Price, \$2.50.

The technical procedures are very adequately presented. Care has been exercised to provide detailed directions which will be welcomed by those wishing to obtain results entirely comparable to those of the author. The means for securing uniformity of the physical state of the diluted antigen is of particular interest.

Some of the tabulations might have been improved had sufficient blood

been collected in all instances to permit the entire series of tests to be made with each specimen.

In addition to the microscopic slide test, a method for a macroscopic procedure is described in which the precipitate collects in the form of a globular mass thus permitting the results to be very easily determined. The use of the centrifuge to hasten the reaction is a distinct contribution.

The conclusions drawn from the comparison of the complement-fixation and precipitation tests performed with the same antigen are open to question since the type of antigen which may furnish optimum results with one of these forms of technic may be entirely unsuitable for the other.

RUTH GILBERT

Correction of Defective Speech—A Complete Manual of Psycho-Physiological Technique for the Treatment and Correction of the Defects of Speech—By E. B. Twitmyer, Ph.D., and Y. S. Nathanson, Ph.D. Philadelphia: Blakiston, 1932. 413 pp. Price, \$3.50.

The authors present a "technique for the correction of all types of speech mutilations" without making any claims in defense of a specific theory. Nevertheless they find a "common factor" which is present in most of their cases: "a disturbance of the normal rhythm of breathing, not only of the costal and diaphragmatic excursions, but also as these, in turn, are synchronized with the modulating adjustments, of the peripheral organs of speech." They emphasize: (a) correct breathing exercises, (b) correct kinaesthetic imagery (oral positions), (c) combinations of (a) and (b) in speech output. The corrective material is arranged so that "no new sound appears in the exercises until the teaching and learning of the previous sound has been acquired." There are distinct

gaps in the evaluation of personality functions and of the total situation in which certain disorders of speech arise.

No attempt has been made to classify speech defects or to describe what constitutes a specific disorder of speech. The etiological topics (Deafness, Amentia, Brain Injury, Anatomical Anomalies of the Organs of Speech, Negativism—"pathological stubbornness") are dismissed with bare descriptive references.

The greater part of the book is composed of carefully selected exercises which are directed toward body coördination, breathing, vocalization, and includes corrective material for the peripheral organs of speech, articulation and integrated speech. An addendum contains suggestions for the treatment of "imitatory acts" by means of a scoring system which is kept by the patient. Here also the personality factors and total situation are minimized in the attempt to lift the act into the field of "volitional performance."

The book is essentially a manual of defective speech training and as such can be recommended for its suggestions as to technic and its excellent collection and arrangement of corrective material.

JACOB H. CONN

Poliomyelitis—Survey by The International Committee for the Study of Infantile Paralysis. Baltimore: Williams & Wilkins, 1932. 562 pp. Price, \$6.00.

The International Committee for the Study of Infantile Paralysis organized by Jeremiah Milbank has summarized the available knowledge and the results of its own investigations in book form. The organization of the material has been performed excellently so that the subject matter presents the disease as a whole. It is divided into chapters concerned with the history, etiology, resistance and immunity, symptom-

atology, treatment, pathology, and epidemiology, each of which is extremely well written. There are an extensive well-keyed bibliography and a detailed index. Poliomyelitis is really summarized in this work which is highly recommended. EDWIN O. JORDAN

Nutrition Service in the Field—Child Health Centers: A Survey—Report IC of the Committee on Medical Care for Children of the White House Conference on Child Health and Protection. New York: Century, 1932. 196 pp. Price, \$2.00.

Two reports on Child Health and Protection are included in this volume. The first section of the book presents the findings and recommendations of the Sub-committee on Nutrition, of which Lucy H. Gillett was chairman. The place, qualifications, and training of the nutritionist in the field of child health are defined clearly. Her services are summarized under the following heads: (1) Promotion and general educational work in the community. (2) Organization and executive work. (3) Instruction, supervision, and consultation—interpreting scientific facts. (4) Direct service—advisory service for individuals and families in connection with nutrition and budget problems. (5) Research—planning and conducting research in the field. Examples of outstanding nutrition services in national, state, and local communities are described, and a section is given to nutrition work in hospitals and dental infirmaries.

The second part of the book is devoted to the report of the Sub-committee on Health Centers, which was presented to the Conference by Dr. J. H. Mason Knox. It is replete with interesting information based upon an extensive study of child health centers throughout the United States and its possessions.

The report defines a health center as "a place where infants and children are examined and parents or guardians given such advice as will promote and protect the health of their children. The service in a typical center is preventive and does not include the treatment of disease." The geographical distribution of 1,511 health centers with the source of support is given in tabular form. The nature and scope of the centers are indicated.

An excellent summary with recommendations is included. The appendix contains a copy of the questionnaire, an analysis of the centers receiving white and negro children, and health centers in Hawaii, Porto Rico, Alaska, and the Philippines. RICHARD A. BOLT

Endocrine Medicine — By William Engelbach, M.D. Foreword by Lewellys F. Barker. Three volumes and an index volume. Springfield, Ill.: Thomas, 1932. Price, \$35.00.

This treatise comprises the results of Dr. Engelbach's observations during his life as a teacher and investigator. While a great deal is naturally the result of the investigations and clinical findings of a host of others, yet he has so woven his own observations in with these, that as a result, we have the most instructive system of endocrinology published in recent years. Certainly nothing of its magnitude has been attempted since *Endocrinology and Metabolism*, by Barker, Mosenthal, and Hoskins, appeared in 1922.

In Volume I, the author discusses briefly the history of this branch of internal medicine, followed at considerable length by the organology and the physiology of the endocrine system. Following this come etiology, diagnostic procedures, and the relationship of endocrinology to general medicine and the several specialties. Lastly, there is a discussion of the relationship of endocrine disorders to public health.

In writing of the relationship of endocrinology to general medicine, it is pointed out that there are few of the various systems in the body that are not affected in some way by this system of glands.

While the treatment of the public health aspects of endocrinology is all too brief, the point is made most emphatically that much can be done by everyone in the several branches of medicine, especially by the general practitioner, to prevent the economic waste and human sorrow due to endocrine disturbances. At a very conservative estimate, the condition of 782,000 of the 10,000,000 defective children in the United States is due directly to endocrinisms, and to a certain extent, these disorders play a part in other forms of defectiveness. From this standpoint the appalling cost of this condition to the taxpayer is emphasized.

In few instances in works of this kind, outside of books devoted to psychiatry and child guidance, does one find such a frank recognition by the author of the bearing of endocrine imbalance upon the social reaction of the child. This brings in its wake the many problems of maladjustment, incorrigibility, crime, and other types of social ills. Special emphasis is here placed upon the need for more careful prenatal and postnatal care from the endocrinological aspect so that these defects may not all be transmitted to succeeding generations.

Volumes II and III are devoted to the consideration of the clinical aspects of endocrine dyscrasias in the infant, the child, the adolescent, and the adult respectively. Here the author makes free use of numerous pictures, tables, charts, and case histories to clarify the subject matter of the text. Of special interest are the excellent anthropometric tables which the author has worked out for the tabulation of growth abnormalities.

It would seem that the subject has been treated in quite a voluminous manner. Such, however, is not the case. No doubt much more could be written which would be helpful, yet the exposition of the subject is excellent.

Certainly no recent work upon the subject of endocrinology has given the medical profession such a complete review as has this work. Free use is made of experimental physiology to help clarify this most complicated subject. For this reason, it should appeal to the clinician as well as to the worker in pure science. While the discoveries of the future may modify or change certain concepts, yet the attitude of the author is that of one trying to base his opinions upon facts proven in the laboratory, instead of indulging in hypothetical conjecture.

If any criticism is to be offered, it would seem that too little attention has been given to the subject of the suprarenal and its diseases, especially in view of the recent work done upon this gland.

The physical make-up of these volumes is excellent, the printing easily legible, and the illustrations profuse and adequately illustrative of the various endocrinopathies.

EDGAR D. BASKETT

International Health Year-Book, 1930, Vol. VI—League of Nations, Geneva, 1932. Available in the United States only through the World Peace Foundation, 40 Mount Vernon Street, Boston, Mass. 1100 pp. Price, \$6.00.

This sound and thorough report upon the status of the world's health during the year 1930 presents a record of outstanding value for the use of reference libraries and for statistical and administrative departments of public health agencies and organizations. The statistical section gives data for each country on population, births, mor-

tality, causes of death, infant mortality, and special information which may be available in individual countries reflecting health status in some particular field. A second section of the report for each country describes the campaign against those acute and chronic diseases which are receiving most attention from public health authorities in the country in question.

Each country reports also upon its activities in the field of social medicine and public health, presenting a description of activities of special interest in relation to such topics as Maternity and Infancy, Health Conferences, Training of Personnel, Demonstrations, Sanitation, School Health, Health Education, and Industrial Hygiene. Some countries report upon hospital, sanitary, and other activities in the field of curative medicine. All report upon public health legislation and the budget. The tables are well organized and systematized. The factual material is carefully selected, and clearly stated.

The countries covered in the report are Australia, Belgium, Bulgaria, Chinese Republic, Czechoslovakia, Denmark, Egypt, Estonia, Finland, France (including French Colonies), Germany, Greece, Hungary, Irish Free State, Italian Colonies, Japan, Latvia, Lithuania, Mexico, The Netherlands, New Zealand, Norway, Poland, Spain, Sweden, Switzerland, Turkish Republic, Union of Soviet Socialist Republics, United Kingdom (England and Wales, Scotland, Northern Ireland), United States of North America, Yugoslavia.

C. E. TURNER

Cancer Then and Now—New York City Cancer Committee, 1932. 80 pp. Price, \$1.00.

An interesting and informative pictorial exhibit on cancer was prepared in 1931 by the energetic New York City Cancer Committee. The material, consisting of charts and photographs

depicting the development of our knowledge of cancer, has been assembled in this attractively printed pamphlet. Each chart has been supplemented with a brief essay on some aspect of cancer control, prepared by an authority in the particular field. While less complete than recent popular texts on cancer, this excellent pamphlet will prove to be invaluable to any person concerned with the prevention and cure of malignant diseases, and it will be of general interest to health educators.

JAMES A. TOBEY

Your Hearing: How to Preserve and Aid It—*By Wendell C. Phillips, M.D., and Hugh Grant Rowell, M.D. New York: Appleton, 1933. 232 pp. Price, \$2.00.*

This is an excellent book, informative and instructive to the deaf, to physicians, especially those in school work, to the social worker, the psychologist, and the layman in general. The style is never stilted nor confusing; the presentation of the various problems is scholarly and could well be imitated in treatises of a strictly medical nature.

There is given a view of the wide extent of deafness, estimated at 3,000,000 school children and 17,000,000 adults. Full discussion follows of the causes of deaf-mutism and the usual degrees of deafness. The hearing apparatus, its anatomy and functions are illustrated and explained. A very complete description of methods for testing hearing, especially the various forms of electrical audiometers, is given, with an explanation of their use and value in different cases. Next is a discussion of the types and classifications of deafness, and an honest statement of the ability and limitations of the physician in treatment is given. Then comes an important chapter on the care of one's own ears with advice, and warning of the dangers of self-treatment. Of particular interest are

the pages on the dangers of bathing, diving, polluted waters, colds, and contagious diseases.

In the chapter on education of the hard of hearing, special stress is laid on the concept that they are to be regarded as mentally normal, and, for psychological and pedagogical reasons and results, should be educated not alone, but with other children.

Good description and history of lip-reading, its applications and values, gives an insight into this method of approach. Particularly important is a full discussion of possible resultant mental abnormalities, their recognition and adjustment by proper and experienced employment agencies, and modern programs of conservation of hearing. Of interest and value to the industrial worker are the chapters on the hazards in the metal, textile, transport, and building industries, regulations against hazards, and lists of favorable trades for the deaf. A chapter deals also with the problems of home and marriage. Especially instructive are chapters on the mechanical and electrical apparatuses that may aid the deaf, which give tests to safeguard the purchaser against improper choice, and warn against the quackery of playing on the hopes and ignorance of the deaf.

JEROME MEYERS

Hookworm Infection—*By Clayton Lane, M.D. London: Oxford University Press, 1932. 319 pp. Price, \$6.25.*

This work is a monument to one who has done extensive personal investigation in a peculiar field of medical science. The author is to be commended for his distinctness and clearness of expression. The homely comparisons vividly deliver pointed facts to the reader. The chapter on diagnosis is particularly comprehensive, of practical value to the clinician and records much personal research. The author's

investigational records may well stand as a guide to the scientific control of tests and technic. The contents of the entire volume should be familiar to every hygienist, and the chapter on prevention should be made known to landlords, mine operators, property owners, renters, landworkers, agriculturists, and all others responsible for the proper disposal of feces, and the tenets prescribed be rigidly enforced.

While the author lists and describes infection in man occurring by mouth, it is peculiar that in the chapter on prevention he does not discuss the means of guarding against this. To the reviewer there are two outstanding sources of such oral infection—that of the clay eater, and that of the consumption of raw vegetables and soil contaminated raw fruits—both of which may become infectious by night soil, natural privies, or dissemination from other unsatisfactory privies.

The book carries an extensive bibliography; and its contents are well grouped under distinctive headings and sub-topic headings.

M. PINSON NEAL

How to Budget Health—By Evans Clark. New York: Harper, 1933. 328 pp. Price, \$4.00.

Here is the specific proposal toward which the accumulating volumes of research have been pushing us. Evans Clark with the practical urge of the Twentieth Century Fund behind him has summarized and interpreted the reports of the Committee on the Costs of Medical Care, and then pictured the application of the major recommendations in terms of persons and services and dollars.

In the 15 chapters and helpful appendices the author has concentrated an abundance of sound sociology and economics. Of course he does not propose a health budget, and he uses the term "guild" in a way that varies from

the connotation of the ancient professional and trade guilds of Europe, but he does create a trustworthy background of fact, quoted largely from the publications of the Committee on the Costs of Medical Care, and then he leads the reader through the common experience of haphazard payment, and uncertainty of quality of medical care today, to look with some hope and ambition toward a better medical responsibility and a more reliable basis of payment by patients.

Evans Clark proposes the creation of groups of physicians associated for service through the facilities of a hospital of the community used in common by them, to offer to groups of potential patients of the local population all necessary medical treatment and diagnosis for preventive care as well, at an agreed annual or monthly fee on the basis of voluntary insurance without the intervention of government dominance or of commercial exploitation.

Between no other covers can one find in so small a compass so useful and stimulating a proposal, certain to be pondered seriously by both doctor and patient, that is, by all of us.

HAVEN EMERSON

Books for Tired Eyes—(2d ed.) Compiled by Charlotte Matson. Chicago: American Library Association, 1931. 59 pp. Price, \$.50.

This brief volume presents a listing of books printed in 14-point type, got up especially for those who find smaller type fatiguing. The list includes topics under the following headings: Fiction; Biography; Travel, Adventure and Out-of-Doors; Literature; History; Books of General Interest; Books for Young People. Also included is the Clear Type Series—books printed in 24-point type which are in general use in sight-saving classes, where only the most legible of type can be utilized.

ISOBEL JANOWICH

A SELECTED PUBLIC HEALTH BIBLIOGRAPHY WITH ANNOTATIONS

High Calcium, High Vitamin Diet—"The average American dietary is poor in calcium content. . . .

Without milk or cheese in the diet it is difficult to obtain the needed calcium through food alone. Utilization of calcium is ineffectual, even with a sufficient calcium intake, unless the factors that control the absorption of calcium are also adequate."

BERNHEIM, A. R. Calcium Need and Calcium Utilization. J.A.M.A. 100, 13:1001 (Apr. 1), 1933.

Colds Lead Them All—A country-wide sample of 8,000 odd families surveyed for a year gave a sickness rate of 850 per 1,000. Many important findings are recorded in this valuable research which confirms in the main the more limited sampling of the Hagerstown studies.

COLLINS, S. D. Causes of Illness in 9,000 Families, Based on Nation-wide Periodic Canvasses 1928-1931. Pub. Health Rep. 48, 12:283 (Mar. 24), 1933.

Bran as a Source of Fibrous Roughage—A good word is said for the laxative value of bran by one who was numbered among the doubters. Except in cases of ulcerated or highly irritable colon, the authors feel now that bran is indicated in constipation. In many cases a diet high in green and fibrous vegetables is not sufficient.

COWGILL, G. R. and SULLIVAN, A. J. Further Studies on the Use of Wheat Bran as a Laxative. J.A.M.A. 100, 11:795 (Mar. 18), 1933.

Group Medical Services Grow—This month the Welkin rings with discussions of social medicine. This paper is a valuable contribution as a record of successful ventures in group hospitalization and medical practice.

DAVIS, M. M. Organized Action in Medical Care. Survey Graphic 22, 4:207 (Apr.), 1933.

The Hague's Refuse Disposal—How the streets are kept clean in that country we think of as the acme of cleanliness is interestingly told. Slovenly American communities will think it an unattainable counsel of perfection.

DEGROOT, V. Street Sanitation in Holland. Municipal San. 4, 3:86 (Mar.), 1933.

The Decline and Fall of Diphtheria—The record of deaths from diphtheria in England from 1881 to 1931 is presented, together with case reports, for the edification of those who may care to compare experience here and there. They will derive comfort from the comparisons.

FORBES, J. G. A Survey of Diphtheria in England and Wales. J. State Med. 41, 3:131 (Mar.), 1933.

Potency of Toxoid Varies—Apparently all diphtheria toxoid is not equally potent. The author found one product distinctly inferior to four others in a comparative test. This is a subject into which health officials would do well to inquire.

GREENGARD, J. The Effectiveness of Commercial Diphtheria Toxoid in Active Immunization of Infants. J.A.M.A. 100, 11:793 (Mar. 18), 1933.

Air in Home and School—The author tells in minute detail how he keeps his residence at a temperature of 62° to 64° F., adding radiant heat to rooms only when, and as, occupied. Over a 10-year period the sickness record of his large family living under these conditions has been good. An interesting contrast between factors in

the adequate ventilation of home and school is presented.

HAYHURST, E. R. Air-Conditioning With Relation to Comfort, Health and Efficiency. *J. Indust. Hyg.* 15, 2:98 (Mar.), 1933.

Eating for Healthy Teeth— Another summary of the rôle of diet in preventing decay of the teeth; a story which cannot be too often retold as long as the "clean tooth" fallacy returns to haunt its guilty perpetrators.

LYONS, D. C. Diet and Decay of Teeth. *Am. J. Nurs.* 33, 3:203 (Mar.), 1933.

Smallpox—Old Style— What hemorrhagic smallpox can do when it pops up in an unvaccinated community is told in this symposium on a recent Canadian outbreak with 56 recorded cases and 17 deaths—a fatality rate of 30 per cent.

McINTOSH, J. W., *et al.* The Vancouver Outbreak of Hemorrhagic Smallpox. *Canad. Pub. Health J.* 24, 3:105 (Mar.), 1933.

The Insidious Menace (?) of Public Health to Private Medicine— The Sage of Baltimore takes a pot-shot at the recommendations of the Committee on Costs of Medical Care in true Menckonian fashion with gratuitous gibes at the reprehensible proclivities of health workers who offer demoralizing social services to all and sundry. Whether you are infuriated or amused, you will find the article good for the soul.

MENCKEN, H. L. What's Going On in the World. *Am. Mercury* 28, 3:257 (Mar.), 1933.

When Crude Death Rates Lie— "A man dies of influenzal pneumonia; at autopsy a very early cancer of the kidney is found; this death will be recorded . . . as being caused by cancer." "If diabetes is mentioned, even as a secondary cause . . . diabetes will get the credit." These are two reasons why statistics do not mean what they seem to mean.

MILLER, J. R. Do Official Death Rates for Diabetes, Cancer and the Puerperal State

Accurately Reflect Present Conditions? *New Eng. J. Med.* 208, 9:490 (Mar. 2), 1933.

Tuberculosis Prevention Surveyed— This is a general review of the modern developments in tuberculosis control presented to a university group in readily understood words, though it could hardly be designated a popular summary.

MYERS, J. A. Recent Developments in Our Knowledge of Tuberculosis. *Am. Rev. Tuberc.* 27, 2:121 (Feb.), 1933.

When Do Children Grow?— Maximum increase in weight occurs in the fall, less in the winter and least in the spring. During 8th and 9th years boys grow a little faster than girls, but in the 10th year girls put on speed until the 14th when boys again forge ahead. Other worth-while observations are recorded.

PALMER, C. E. Seasonal Variation of Average Growth in Weight of Elementary School Children. *Pub. Health Rep.* 48, 9:211 (Mar. 3), 1933.

Preventable Causes of Maternal Deaths— This article on what's wrong with maternal hygiene administration has some far reaching implications. For instance, "It is an incontrovertible fact that certain discoverable functional defects render a woman unfit for pregnancy or delivery. . . . To know the danger and to refuse to protect her from it is to practise, not enlightened medicine, but ancient or medieval philosophy, on the altars of which every year certain women are sacrificed." The paper is reprinted in the current issue of the *Medical Officer*, 49, 10 (Mar.), 1933.

ROCK, J. Maternal Mortality. *The Commonwealth (Mass.)* 19, 4:171 (Oct.-Dec.), 1932.

A Savage Rejoinder to Pasteurization Opponents— "There is nothing in any of these experiments to indicate that any unknown substance is de-

stroyed by pasteurization. All the results (such as they are) are explainable on a diminution of calcium and phosphorus fed to experimental animals whose need of these substances is much greater than man. They offer no evidence which can be applied to man." The remainder of the paper discussing the practical bearing of pasteurization upon child nutrition appears in the succeeding issue.

SAVAGE, W. G. The Effect of Pasteurization Upon the Nutritive Properties of Milk. *Lancet*, 224, 5713:429 (Feb. 25), 1933.

Potent Arguments Against Socialized Medicine—An effective, convincing presentation of the arguments against the proposals of the Committee on Costs of Medical Care, avoiding all the invective and billingsgate that have marred so much of the discussion by the opponents of the majority schemes. It should be read critically and conscientiously by all health workers.

SCHWITALLA, A. M. Basic Considerations in Minority Report of Committee on Costs of Medical Care. *J.A.M.A.* 100, 12:863 (Mar. 25), 1933.

NEWS FROM THE FIELD

SUMMER SCHOOL COURSES IN PUBLIC HEALTH

While the following list does not show all universities and technical schools offering summer courses in public health, it represents those who have replied to a questionnaire sent out by the American Public Health Association.

American National Red Cross

Courses in Teacher Training for Home Hygiene Instructors:

- University of California, Los Angeles, Calif.—June 28–August 9
- Colorado Agricultural College, Fort Collins, Colo.—July 10–August 19
- Pennsylvania State College, State College, Pa.—July 3–August 11
- Syracuse University, Syracuse, N. Y.—July 5–August 12

The National Society for the Prevention of Blindness

Courses to prepare teachers for the education of children with seriously defective vision:

- University College, University of Chicago, Chicago, Ill.—June 26–August 1
- Teachers College, Columbia University, New York, N. Y.—July 10–August 18
- Western Reserve University, Cleveland, O.—June 19–July 28

University of California, Berkeley, Calif.

June 26–August 4

- Elementary Epidemiology
- Elementary Public Health
- Management of the Hospital Unit
- Supervision in Hospitals and Schools of Nursing

University of Chicago, Chicago, Ill.

June 19–August 25

First Term: June 19–July 21

Second Term: July 24–August 25

- Teaching the Principles and Practices of Nursing

- Supervision in Schools of Nursing
- Ward Management and Teaching
- General Bacteriology
- Advanced Bacteriology, Parasitology, and Public Health
- Special Public Health Problems
- Preventive Medicine and Immunology
- Introduction to Nutrition
- Nutrition
- Clinical Nutrition
- Seminar in Food and Nutrition
- Child Care
- Child Development and Training

Columbia University—DeLamar Institute of Public Health, College of Physicians and Surgeons, New York, N. Y.

June 12–30

- School Health Supervision—Medical Inspection, Mental Hygiene, and Physical Education

Teachers College, New York, N. Y.

July 10–August 18

GERMS NOT KILLED BY LIQUID HELIUM

EXTREMELY low temperatures, approaching those believed to exist in interstellar space, failed to kill bacteria in tests at the University of Toronto. Germs frozen for weeks in liquid helium, at a temperature of about 450 degree below zero Fahrenheit, proved to be alive and able to multiply as though nothing had happened to them, as soon as they were thawed out.

These results are taken as indicating at least the possibility of the lower forms of life migrating through space, perhaps attached to bits of dust. They are of more immediate practical value as demonstrations of the fact that though cold will preserve foodstuffs it will not kill the germs of decay that lurk on them.

The experiments were performed by Dr. J. O. Wilhelm, physicist, Dr. H. Wastenays, biochemist, and Dr. W. L. Holman, bacteriologist.—*Science News Letter*, Feb. 11, 1933.

HOOKWORM SURVEY

THE examinations in 8 counties in Mississippi have been completed in a hookworm survey carried on by the Mississippi State Board of Health in coöperation with the department of preventive medicine of the Vanderbilt University School of Medicine, and the International Health Division of the Rockefeller Foundation. The survey was begun September 1, 1932. Twenty per cent of the 8,363 specimens examined showed the presence of hookworm ova. Of those found positive, there was an average of 135 worms per person. Thus far, the results of the survey indicate that intensive parasites are a problem of only the white race, the report stated. Negroes showed less than 2 per cent positive for hookworm ova.—*J.A.M.A.*, Mar. 11, 1933, p. 748.

PERSONALS

DR. ELDRED V. THIEHOFF, a member of the A.P.H.A., has been appointed Acting Director of the Cleveland Child Health Association in the absence of Dr. Richard A. Bolt, who has been granted an award by the Oberlaender Trust for a year's study abroad. Dr. Thiehoff was formerly Chief of the Child Hygiene Service of the Akron City Health Department.

DR. R. E. DYER, of the U.S.P.H.S., was chosen by the Association of Military Surgeons of the United States to deliver the lecture at the Kober Day celebration in Washington, March 28. His subject was "Typhus and Rocky Mountain Spotted Fever."

DR. DANIEL M. BRADLEY, of Waycross, Ga., has been elected Commissioner of Health of Ware County.

DR. WEBB CONN, of Brunswick, Ga., has been elected Health Commissioner of Glynn County.

DR. JAMES ANGUS DOULL, F.A.P.H.A., of the Western Reserve University School of Medicine, Cleveland, sailed March 25 for the Philippine Islands to organize an epidemiologic study for the eradication of leprosy.

DR. SAMUEL MCC. HAMILL, of Philadelphia, member A.P.H.A., has been appointed by Governor Pinchot to the office of Chairman of the Pennsylvania Emergency Child Health Committee to supplement the work of relief organizations, with special emphasis on nutrition.

DR. CHARLES A. NEAFIE, member A.P.H.A., of Pontiac, Mich., has been appointed associate director of health of the State of Maine. Dr. Hubert M. Heitsch, F.A.P.H.A., succeeds Dr. Neafie as director of the Pontiac Health Department, it is reported.

- DR. EUGENE P. KING, second deputy superintendent of health of Providence, R. I., has announced his retirement. Dr. King has been connected with the department for over 40 years.
- DR. W. T. HENSHAW, F.A.P.H.A., of Charleston, has resigned as State Health Commissioner of West Virginia.
- DR. DAVID LITTLEJOHN, F.A.P.H.A., of Charleston, has been appointed as Acting Health Commissioner of West Virginia, in place of Dr. W. T. Henshaw, resigned.
- DR. HUGH C. McREE, for years head of the Morgan County Health Unit, has been appointed Health Officer of Lee County, with headquarters at Opelika, Ala.
- DR. GEORGE L. THOMPSON, of Owensboro, Ky., member A.P.H.A., has resigned as Health Director of Daviess County and is now Health Officer of McLean County. Dr. Lawrence Hubert Medley was elected to succeed him in Daviess County.
- DR. GEORGE HERBERT RAMSEY, F.A.P.H.A., of the Johns Hopkins School of Hygiene and Public Health, Baltimore, has been appointed Director of the Division of Communicable Diseases of the New York State Department of Health.
- DR. HAROLD JACKSON DAVIS, member A.P.H.A., Epidemiologist of the New York State Department of Health, has been appointed director of medical care for the Temporary Emergency Relief Association.
- DR. CHARLES N. DENISON, member A.P.H.A., has been appointed Health Officer of New Hartford, Conn., succeeding Dr. John R. Lee. Dr. Wilbur J. Moore succeeds Dr. Denison as Health Officer of Cheshire.
- DR. JAMES W. BASS, of Dallas, member A.P.H.A., was elected president of the Texas Public Health Association at the recent meeting in Dallas.
- DR. THEODORE SNYPP, of Auburn, Calif., succeeds Dr. David M. Kindopp as Health Officer of Placer County, Calif.
- DR. CHARLES C. DUBOIS, formerly Health Officer of Warsaw, Ind., was elected Mayor recently.
- DR. WILLIAM W. MCFARLAND, member A.P.H.A., has been appointed Director of Health of Pittsburgh, to succeed the late Dr. Charles B. Maits, F.A.P.H.A.
- DR. THOMAS C. LYNCH, of Wichita Falls, was recently appointed Health Officer of Wichita County, Tex.
- DR. WALTER L. BIERING, of Des Moines, Ia., has been appointed State Health Commissioner of Iowa, effective July 1.

DEATHS

CLARENCE A. SHORE, M.D., F.A.P.H.A., of Raleigh, N. C., died on February 10, 1933. For 25 years Dr. Shore was Director of the Division of Laboratories of the North Carolina State Board of Health. He was a native of Winston-Salem, N. C., and a graduate of the University of North Carolina. He received his medical degree from Hopkins in 1907. He built a first-class laboratory, which has rendered invaluable service to the people of his state. In 1929 he was awarded the Doctor of Science degree from the State University as a recognition of his important service in the promotion of scientific progress. He has been a member of the A.P.H.A. since 1909, and a Fellow since 1923.

DR. CHARLES O. PROBST, of Columbus, Ohio, superintendent of the Franklin County Tuberculosis Sanatorium, died on April 2, at the age of 75. He

was secretary of the American Public Health Association for more than 10 years, and was also a former president of the Association. He became a member of the A.P.H.A. in 1886 and a Fellow in 1926.

RENÉ VALLERY-RADOT died on January 24, 1933, at the Hospital of the Pasteur Institute. He was the President of the Council of Administration of the Pasteur Institute of Paris. He is best known to us as a historian and biographer of Pasteur. He was the son-in-law of Pasteur, having married his daughter, Marie-Louise. Apart from his biography, he had a high reputation as a writer, having had special training from his father in this line. He had also made a place for himself as a diplomat.—*Ann. de l'Inst. Pasteur*, Feb., 1933.

DR. L. C. HAVENS, Director of Laboratories of the Alabama State Health Department since 1921, died after a heart attack at his home on March 19, 1933. He was born at Lebanon, N. H., in 1891. He studied at the University of Colorado and Harvard University and was Assistant Professor of Immunology in the School of Hygiene at Johns Hopkins University before coming to Alabama. Dr. Havens has been a member since 1920 and a very active Fellow of the Laboratory Section of the A.P.H.A. since 1931; and has presented papers at our meetings dealing with methods of isolating typhoid bacilli, a subject in which he was an outstanding authority. At the time of his death he was a member of the Committee on Standard Methods.

JAMES R. MCCLINTOCK of the firm of Fuller & McClintock, died on April 11, of a heart attack following an illness of several weeks with influenza and bronchitis. He was educated at the University of Rochester and the

Massachusetts Institute of Technology from which he was graduated in 1906. His entire professional career was spent with Hering & Fuller, the firm of George W. Fuller and the firm of Fuller & McClintock which was organized in 1916. Mr. McClintock was a member of the American Society of Civil Engineers, American Society of Mechanical Engineers, American Institute of Consulting Engineers, American Water Works Association, and the American Public Health Association.

Obstacles in the No-Diphtheria Path*

W. P. SHEPARD, M.D., F.A.P.H.A.

Assistant Secretary, Welfare Division, Pacific Coast Head Office, Metropolitan Life Insurance Company, San Francisco, Calif.

IF tomorrow should give us a positive means of preventing cancer, how would we proceed to tell the public about it? The effectiveness of our method would determine to a large extent the number of lives saved. Ineffective methods would mean continuation of the cancer tragedy.

On the day after the increase in postal rates took effect, the San Francisco Post Office reported that over 10 per cent of letters received had insufficient postage. This was in spite of a carefully conducted program of education by the United States Post Office Department. It took 200 smallpox deaths in 1924 to get the people of Los Angeles reasonably well vaccinated, despite repeated warnings from a generation of health officials. The *New Yorker* states that following an advertising campaign by a tooth paste concern featuring pink tooth brush as a sign of pyorrhea, one drug store had 300 customers try to buy a pink tooth brush! A health officer may well ask,

"When will people learn, and, how do they learn?"

During the last 15 years, we have sought many practical answers to this question in our efforts to eradicate diphtheria. Compared with smallpox vaccination, which was violently opposed for much more than 15 years, our method is greatly improved. Perhaps omission of compulsion early associated with smallpox vaccination accounts for this in part.¹ Be this as it may, diphtheria eradication is far from an accomplished fact, especially in western United States. With all due credit for our success, perhaps a study of our failures will prepare us to do a better job in the future when we are called upon to inform the public of a new discovery and are obliged to use our ingenuity to persuade people to do what we tell them.

WESTERN DIPHTHERIA IMMUNIZATION STATUS

With a view to estimating both successes and failures in the anti-diphtheria campaign in the West, a study was undertaken late in 1930, to ascertain by a sampling method how many children of susceptible age had been immunized in

* Read before the Health Officers Section of the American Public Health Association, at the Sixty-first Annual Meeting in Washington, D. C., October 26, 1932.

various western localities, by whom they had been immunized, and, finally, the reasons why a considerable proportion remained unprotected.

With the approval of the Manager of the Pacific Coast Head Office and the Welfare Division of the Home Office of the Metropolitan Life Insurance Company, the agents in various localities, from Denver west, and Seattle south, were asked to conduct a diphtheria immunization census. Blanks were furnished for this purpose, on which the agent was to list the name and address of the family contacted, the number of children in the family with their ages, the number immunized, by whom immunized, and reason given by the householder why the unprotected children had not been immunized. Agents were instructed to interview both policyholders and non-policyholders in a given block within a designated 2-week period, obtain the

centers. Their immunization status is illustrated in Chart I. This chart shows that of 6,245 children, 1,496, or 24 per cent, had been immunized, while 4,749, or 76 per cent, were not. There was, of course, considerable variation from city to city.

Of the 1,496 immunized, 1,266 reported "by whom" immunized. Among these 760, or 60 per cent, had been treated in the school clinics; 333, or 26.3 per cent, by private physicians; 168, or 13.3 per cent, by other public clinics; 5, or 0.4 per cent, by the industrial physician (Chart II).

The 4,749 children who were reported not immunized included 1,958 families from whom satisfactorily completed answers to the question, "Why not?" were obtained. Among the reasons given, a total of 76 different phrases, many of them meaning the same thing, were used. It was found that these 76 phrases could be divided

data requested, and return the reports to the head office. Satisfactorily completed blanks were eventually obtained for 6,245 children between the ages 6 months and 15 years, scattered throughout the West, largely in urban

somewhat arbitrarily into 5 main classes, as follows:

Lethargy: Including such reasons as "neglected," "may later," "too much trouble," "overlooked," "not convenient," etc.

Ignorance: Including such reasons as "never

knew of it," "not exposed," "not convinced," "had diphtheria," "not of school age," etc.

Opposition: Including such reasons as "opposed," "don't want," "religious objections," "made friends ill," "previous unsatisfactory experience," etc.

Economic: Including such reasons as "can't afford," "not offered free," "will if free clinic available," etc.

Legitimate Medical: Including such reasons as "illness," "negative Schick," "doctor advised against," etc.

In making this arbitrary classification the border-line between causes attributable to lethargy and ignorance was not always clear; nor the line between economic objection and other opposition. However, the difference between active opposition, from whatever cause, and psychic indolence was usually clear. It is, of course, realized that the reasons given to agents may not always have been true ones, but at least the error in each case is reasonably comparable. It is believed that these reasons shed some light on the ineffectiveness of certain diphtheria immunization programs.

When thus classified, it was found that 979 or 50 per cent of the reasons

could be attributed to lethargy; 406 or 20.7 per cent to ignorance; 424 or 21.7 per cent to opposition; 131 or 6.7 per cent to economic reasons; 18 or 0.9 per cent to legitimate medical reasons (Chart III).

It will be noted that ignorance and lethargy account for 70.7 per cent of the failures of these families to have their children protected. Certainly, these causes of failure are a challenge to the health worker. If we could inform our public of the value of diphtheria protection, and do it in precisely the right way, over two-thirds of our failures could be abolished.

As to the 22 per cent showing active opposition, certainly many could be won over. Only 3.5 per cent of the total admitted objection on religious grounds. Although this may be a deceptive figure, experience teaches that even religious objections can sometimes be overcome when properly approached. Possibly this surprisingly high percentage of opposition is due to the prevalence of cultism in the West, especially in Southern California. This large percentage of opposition also

brings up the question of whether our attempts to educate the public are resulting in a certain degree of negativism. It may be that something in our method is so objectionable as to lose rather than gain certain recruits to our cause.

the hope that we can improve our methods.

LIMITATION OF MASS SELLING

Diphtheria immunization, like many other portions of the health information program, is at least in part a sales job.

Certainly the economic objection amounting to 6.7 per cent is within the province of most health organizations to remedy. The legitimate medical objections give us no cause for concern.

These proportions are not dissimilar to a study made by the Oklahoma State Health Department covering 892 failures to immunize.²

COMMENT

It would seem that there is room for improvement in our present method of informing and activating the public in the matter of diphtheria protection, at least in the West, and it is assumed that we are not unique in this regard. It appears that there are peculiarities of public receptiveness which we do not always appreciate. It is incumbent upon us as health informants to examine these peculiarities with care in

Sales experts agree that so-called "mass selling" is the quickest and most economical way of reaching the public. One wonders if we have not been misled by this philosophy. So much of our health propaganda, including diphtheria information, constitutes a broadside aimed at the public in general. Much of this broadside must fall on deaf ears.

It is common procedure, for instance, in promoting an anti-diphtheria campaign, to make extensive use of newspapers, radio broadcasts, placards, billboards, street car signs, etc. When we come to analyze the actual number in the group we are attempting to motivate, it seems questionable whether this method is so effective after all.

For instance, San Francisco has a population of 634,394.³ Of this number, 33,860 are over 65 years of age, few of whom would be responsible for

children between the ages of 6 months and 15 years; 119,308 are single men who are obviously not interested; 65,311 are single women; 159,056 are minors, under 21 years of age, in whom we are not directly interested. Since our chief concern in the matter of diphtheria immunization is to reach parents with children between the ages of 6 months and 15 years, we can deduct these childless persons, 377,535, from the total population, leaving a balance of 256,859 persons in this city who are married and under the age of 65. This number includes many childless couples so that the number of individuals whom we desire to reach is probably not over 225,000. Now, it is not usually necessary to convince both parents of the importance of diphtheria immunization. As a rule, if we reach either the mother or father effectively, the job is done. It will be seen that there are not many more than 120,000, about 20 per cent of the population, whom we wish to inform and motivate. And yet we issue a broadside aimed at 634,394!

The illustration can be made even more impressive if we bear in mind that the diphtheria problem is really solved if we can but immunize 70 to 80 per cent of all children at the age of 1 year and continue this for 10 years. In San Francisco there are only 5,816 children under 1. This means immunizing an average per month of only 484! Forty nurses need make personal calls on only about 3 per week apiece.

In a recent health education campaign, worked out with unusual care, in New York City under the supervision of Commissioner Wynne, parents were furnished through their school children with "teasers" offering further information on various aspects of healthful living. They were asked to fill out a card with their names and addresses and check the items in which they were particularly interested. It is reported that about 2 per cent responded.⁴ Even

this is considered satisfactory, since most advertisers are elated when they obtain 1 per cent response in matters of this kind. One per cent or 2 per cent response to our anti-diphtheria propaganda is disappointing, to say the least.

To be sure, there is a certain charm in widespread newspaper articles, and especially in street car placards and billboard signs. To those of us who are responsible for designing and placing these signs, they are gratifying, and make us feel that we are really doing something. Perhaps this is a form of self-hypnotism which we must not allow to mislead us. Such methods undoubtedly have some value as a miscellaneous background, but cannot replace the personal appeal.

INDIVIDUAL VS. MASS SELLING

We find in current public health practice some noteworthy examples of the effectiveness of individual selling as opposed to mass selling. It is more expensive, but at the same time is less extensive. The visit of the public health nurse and social worker to the home of the known case of tuberculosis has proved extremely effective. Most of our infant and maternal hygiene program has been limited by its very nature to a selected group, among whom individual selling is effectively done. For obvious reasons, we do not attempt to use newspaper articles, billboards, and street car placards to urge the expectant mother to report to a given clinic. The real effectiveness of quarantine depends upon individual instruction by the health officer's deputy or the public health nurse, rather than upon passing ordinances and police notification. The powerful health education influence of bedside nursing has been felt throughout the country. Even in the notable diphtheria experience of Vaughan⁵ in Detroit, most effective results were obtained both with the

public and with the physician when personal contact was made.

SOME FACTORS INFLUENCING PUBLIC RECEPTIVENESS

Five years ago we had the benefit of an excellent symposium on "Steps in Planning a Health Education and Publicity Program."⁶ Unfortunately, it was not presented to the Health Officers Section. The concluding paragraph of Winslow's paper in this symposium is worth reviewing:

The object of our whole program is, I take it, to change the conduct of individual men, women and children. . . . We are interpreters between the vast resources of health and science on the one hand and the individual in the home and factory on the other. We must keep both things in view. We must believe in both. We must have faith in the message we deliver. As Richard Cabot once said, I think, of social service, "We must feel that we have something 'too hot to hold.'" We must also believe in the educability of the common man, or our efforts will be spiritless and futile. It is these two faiths after all—faith in the cause and faith in human nature—which make the health educator. Whatever our technic, whatever our rigidity of self-criticism, we must add at the end that quality of enthusiasm—a word which in its derivative sense means an inward God. The work of translating the lessons of science into human conduct is indeed a godlike one. If we fully realize its significance, we shall not fail.⁷

Professor Franklin Fearing⁸ pointed out some of the fundamental psychological reactions among which we must operate when informing the public about health: that whether we like it or not, people have what are called "attitudes" concerning health and other matters, which may be characterized as follows:

They tend always to express themselves in actions, to have a strong emotional coloring. They do not involve rational processes as an antecedent to action. They may be conscious or unconscious. They are associated with and

easily released by symbols, signs, slogans, phrases, catch words, and pictures. Where fundamental attitudes are involved, the response is out of proportion to the intensity of the stimulus. They may be developed as a result of a single experience or they may be established by systematic and persistent propaganda.

PUBLIC HEALTH ATTITUDES AND SYMBOLS

What are the attitudes toward health matters of this 22 per cent who indicated active opposition to diphtheria immunization? What are the attitudes of the 70 per cent who indicated lethargy or ignorance? Many of them must be unfavorable. How much have we done to create these unfavorable attitudes? How much have we done intelligently to overcome them? It is safe to say that the symbol associated with the attitude in the minds of many of these people is probably a painful looking hypodermic syringe, or a disagreeable red quarantine sign, or perhaps a disagreeable odor of disinfectants and guinea pigs, or perhaps a stern visaged health department nurse, or a hard-boiled sanitary inspector, or even a policeman who once called at their house in connection with health department matters. Perhaps their attitude to the health department is merely impassive and so feeble that it cannot express itself in action.

It would seem that we lack effective symbols in public health which could activate proper attitudes. Thus a symbol which means so much to us who know its history may mean to the general public the senseless strapping of a helpless child to an uncomfortable looking board with enough bandages around its body to make it look like an Egyptian mummy. Even the caduceus, so eloquent and satisfactory to physicians, may mean nothing but two

snakes wound around a stick to the public.

On the other side of the picture there is the Red Cross, an international symbol of succor and mercy. There is the health center, coming to mean as it has in recent years an attractive building with pleasing architecture, a touch of landscaping, attractive furnishings, and cordial, polite attendants. There is the almost universal earnestness of the average health officer and other health worker as he or she stands before an audience, pleading the cause of health. These and many others which could be cited are productive of correct attitudes and helpful symbols in the public mind. Our job is to search for more of them.

Galdston⁹ has pointed out that we are in error when we assume that the public mind can be likened to an empty vessel standing upon a shelf waiting to be filled with knowledge. He points out that the human mind is dynamic, not static; and our task is more like that of the batter who attempts to strike a moving baseball than of the billiard player who strikes at a still ball. He calls attention to the fact, however, that the public mind, like the baseball, will usually follow a given direction and a limited number of curves. It is these directions and curves which we must study in order to make a hit.

SUCCESSFUL ANTI-DIPHTHERIA MEASURES

Applying this to our diphtheria problem, space will permit but a few specific illustrations of the procedures which are likely to be successful.

Not many years ago, a remarkably successful anti-diphtheria campaign was conducted in New York City. One of the most effective things done was to obtain a highly decorated and beautifully printed letter from the Catholic Archbishop which exhorted his

parishioners to avail themselves of this protection for their children. This is recalled because we often fail to obtain the support of religious advisers, whom some people will follow more quickly than anyone else.

The testimonial method of advertising, regardless of the furor it has caused in scientific circles, has back of it a deliberate and well planned attempt to take advantage of known psychological principles.¹⁰ One of the first things attempted by those who made a survey of health education in the Philippine Islands recently, when it was decided that the prevalence of beri beri could best be controlled by persuading the public to eat unpolished rice, was to obtain a photograph of the Governor General of the Islands eating unpolished rice.¹¹ This would seem a most legitimate use of the testimonial method of mass selling, and one wonders why it has not been used more frequently in health promotion.

It would be comparatively simple to obtain photographs of the children of prominent citizens being immunized. Advertisers have found that persons of prominence are rather open to the argument that what they do, to some extent at least, sets the pattern for what others will do in their locality.^{12, 13, 14} Certainly there should be much less difficulty with this argument when used in favor of a plan which will save life than would be the case when used in connection with a plan to sell more of a certain cold cream. It might even prove cheaper to the health officer than to the advertiser.

The now well established practice in many health departments of sending letters, urging diphtheria immunization, to the parents of 1-year old children is an effective measure which illustrates the value of individual selling. When this letter is followed by a visit from a nurse, it is still more effective.

UNSUCCESSFUL ANTI-DIPHTHERIA MEASURES

Procedures which seem less likely to be successful are use of the fear motive, the imperative and official tone often used on health department consent slips, extended public controversy with the "antis" and exclusive reliance upon mass selling which tends to annoy those not concerned. Possibly these are mistakes which account for some of our active opposition.

SUMMARY

To summarize, every activity undertaken to promote an anti-diphtheria campaign should be carefully scrutinized to eliminate objectionable methods through which we may be unwittingly repelling potential supporters. The more individual selling we can do, rather than mass selling, the more effective will be our work. The audience to whom we would appeal is often much smaller than we think; therefore, the cost of individual approach is not so great as might be feared. In estimating the speed, curve, and direction of the ball we wish to hit, we must take account of the known principles of psychology by developing new attitudes and furnishing favorable symbols and stereotypes.

CONCLUSIONS

1. In a sample of 6,245 western children investigated by the agents of a life insurance

company only 24 per cent had been immunized against diphtheria.

2. Of the 1,496 already immunized 60 per cent were treated at school clinics, 26.3 per cent by private physicians, 13.3 per cent at other public clinics, 0.4 per cent by the industrial physician.

3. Of the 1,958 families giving reasons for failure to immunize, 70 per cent might be attributed to lethargy or ignorance, 21.7 per cent to active opposition, 6.7 per cent to economic reasons, and 0.9 per cent to legitimate medical reasons.

4. The underlying causes of failure of parents to immunize their children are discussed and suggestions made for remedy.

Relation of the Use of Milk to the Physical and Scholastic Progress of Undernourished School Children*

FRED F. LININGER, PH.D.

The Pennsylvania State College, State College, Pa.

THE essential place of milk in the human diet is now generally recognized, primarily, it may be noted, because of extensive experimentation with the lower animals. For self evident humanitarian reasons, long-time experiments which involve the placing of large numbers of persons on a milk-free diet are seldom conducted. Basic scientific experimentation upon children by Sherman and Hawley,¹ however, was cited 10 years ago in an editorial, which reads in part²:

The dietary rule of a quart of milk each day for every child is much more than a precept based on individual opinions or drawn by analogy from the results of feeding experiments with lower animals; it now rests on scientific evidence obtained by extensive and intensive experiment directly upon the children themselves.

Further evidence may be obtained by studying the records of progress made by children in those centers where under existing conditions some children receive no milk, and others receive it in varying amounts. This paper, which is a progress report, presents data on the relation of the use of milk to the physical progress of pupils enrolled in special health classes conducted by the Division of Medical Inspection in the Philadelphia public schools over a

2-year period; also some information, rather meager, on the parallel that may be found in the scholastic progress of the same groups. In these classes were enrolled pupils who were 13 per cent or more underweight according to the Baldwin-Wood standards of age, height, and weight. It is a statistical analysis based on the records of gains in weight compiled by school nurses and of scholastic gains reported by teachers. Gain in weight was the only available statistical measure of physical progress. For the 1930-1931 school year there were 2,522 individual records and for 1931-1932, 1,611. Included in the 4,133 records were 931 "free milk cases"—pupils who receive $\frac{1}{2}$ pint of free milk daily in school. The milk consumption of the other pupils ranged from 0 to more than 1 quart daily.

VALIDITY OF DATA AND DESCRIPTION OF SPECIAL HEALTH CLASSES

The special health classes were organized not to obtain experimental evidence, but to promote the health of a large number of undernourished pupils, and the use of milk was only one of many practices followed to achieve this end. An extensive health record was available for each child showing age, apparent financial status of the family, quality of home food, presence of physical defects such as diseased

TABLE I

RELATION OF THE USE OF MILK TO GAINS IN WEIGHT OF UNDERNOURISHED PUPILS
Health Instruction Group, Division of Medical Inspection, Philadelphia
Public Schools—1930-1931 and 1931-1932 School Years

| Milk Consumption Practice | Number of Pupils | Average Semester Gain per Pupil | | Probable Error of Mean Gain |
|--|------------------|---------------------------------|-----------|-----------------------------|
| | | Pounds | Per cent* | |
| I No Milk | 268 | 2.73 | 100 | .09 |
| II All Milk Users | 3,865 | 3.53 | 129 | .03 |
| (a) Free Milk in School | 931 | 3.40 | 125 | .05 |
| (b) Milk at School—No Record of Home Use | 440 | 3.39 | 124 | .07 |
| (c) Milk at Home—No Record of School Use | 1,893 | 3.50 | 128 | .04 |
| (d) Milk at Home and at School | 601 | 3.95 | 145 | .06 |

* Taking 2.73 lb. as a basis for comparison

sils, dental caries, defective vision, nasal obstructions, characteristics of the child's rest period, and the like.

The nurses (approximately 90) who compiled the records, in addition to the regular training required of graduate nurses, received special instruction in nutrition. They were, with few exceptions, experienced workers who had been compiling similar records since 1926. By frequent visits to the homes, they were thoroughly familiar with conditions and food consumption practices.

A brief description of the special health class work is quoted²:

There were 163 such health classes conducted by the nurses, the majority of the nurses succeeding in their attempt to conduct one health class in the fall term and one in the spring term. This plan allows only 4 to 5 months in the health class for each child, although children in the fall classes who fail to gain are often continued as members of the spring health classes.

The gain in weight in the fall months is characteristic. Part of it is real, due to the natural tendency to take on fat during cold weather, with lessened outdoor activity and earlier retiring hours. Part of it may be only apparent, due to heavier underclothing donned with the advent of cold weather. If there is a small error to our apparent advantage during the fall months, at least it may be remarked that the same error in the spring months, due to the discarding of the heavier clothing, correspondingly works to lessen the record of gains in weight, so that the figures

for the whole year are thus balanced and may be taken as accurate.

USE OF MILK AND PHYSICAL PROGRESS

The 4,133 individual records were sorted into 5 groups, based on differences in milk consumption of the pupils as recorded by the nurses. Actual quantities of milk consumed were not obtainable, except for 425 pupils in the 1931-1932 study. In 1930-1931 the average gain of those using milk at home and at school was 29 per cent greater, and in 1931-1932, 84 per cent greater than of those using no milk. Increased gains were associated with the use of milk consistently in both semesters of each year.

Combining data for the 2 years, the average gain per pupil in the group receiving no milk was 2.73 lb. per semester (Table I). When the 3,865 users of milk in varying amounts and from varying sources were grouped, the average gain per pupil was 3.53 lb. per semester, or 29 per cent greater than that of those not using milk. The pupils using milk at home and at school during the 2 years gained 45 per cent more than those not using milk.

For a large number of pupils, records were not obtainable for either the home use or the school use of milk. In group II-b, classed as "Milk at school,

no record of home use," the average gain per pupil was 24 per cent greater than in the "No milk" group. Likely, a rather small proportion of group II-b received no milk at home. On the other hand, doubtless, a large proportion of the group classed as "Milk at home, no record of school use" received no milk at school; the average gain per pupil, however, was 28 per cent greater than in the "No milk" group. The records suggest that the use of milk in the home was more closely related to gain than was the use of the milk in school.

These data were in accord with the results of similar research in Scotland⁴ where milk was furnished as a supplementary food to children in school. In the Scottish experiment, the milk group in 1927 (1,282 elementary school children) gained 21.62 per cent more than the non-milk group; and in 1928 (1,157 children) the milk group gained 45.37 per cent more than the non-milk group.

Age and Gain in Weight—Again in 1930, reporting on an investigation of 20,000 children, 5 to 12 years of age, inclusive, in Lanarkshire schools, Scotland, Leighton, and McKinlay⁵ concluded:

The influence of the addition of milk to the diet of school children is reflected in a definite increase in the rate of growth, both in height and weight.

There is no obvious or constant difference in this respect between boys and girls, and there is little evidence of definite relation between the age of the children and the amount of improvement. The results do not support the belief that the younger derived more benefit than the older children. As manifested merely by growth in weight and height the increase found in younger children through the addition of milk to the usual diet is certainly not greater than, and is probably not even as great as, that found in older children.

It is recognized, however, that the normal gains of adolescent children are larger than those of younger children of school age. In the present analysis of

gains in weight among undernourished children the rule holds (Table II). Those of adolescent age, 12 to 15 years, made greater gains than those under 12 years of age. The differences in gains of undernourished children under 12 years of age, however, were not significant, and confirm the conclusions of Leighton and McKinlay relative to children of this age.

TABLE II

AVERAGE GAINS IN WEIGHT OF UNDERNOURISHED PUPILS BY AGE, HEALTH INSTRUCTION GROUP, DIVISION OF MEDICAL INSPECTION, PHILADELPHIA PUBLIC SCHOOLS—1930-1931 AND 1931-1932 SCHOOL YEARS

| Age | Number of Pupils* | Average Semester Gain in Weight per Pupil Pounds |
|-------------|-------------------------|---|
| 6 | 8 | 2.26 |
| 7 | 73 | 2.85 |
| 8 | 350 | 2.92 |
| 9 | 740 | 3.27 |
| 10 | 730 | 3.39 |
| 11 | 488 | 3.62 |
| 12 | 335 | 4.05 |
| 13 | 227 | 4.54 |
| 14 | 102 | 4.33 |
| 15 | 83 | 3.82 |
| 16 and over | 66 | 2.58 |
| | 3,202 | 3.54 |

* 931 "free milk" cases are not included

In order to note the possible influence of age on gains in weight of the several milk consumption groups, the age distributions of each group were determined. It was found that 30 per cent of the pupils in the "No milk" group (Table I) ranged from 12 to 15 years inclusive, while only 19 per cent of those in the group receiving milk at home and at school were of similar age. Therefore, those who used milk made greater gains than those who did not, not because they were older but despite the fact that they were younger.

For 425 pupils in the 1931-1932 school year, data relative to approxi-

mate quantities of milk consumed daily, rather than merely the milk-consuming practices, were separately analyzed. One hundred eighty-four pupils who received 1 quart or more of milk daily made an average semester-gain of 4.34 lb. per pupil, compared with 3.98 lb. per pupil for 241 children who received less than 1 quart daily. The difference in gains of the two groups, approximately 9 per cent, is in itself not highly significant, but in this comparison also the large users of milk were younger pupils than those using less than a quart. Only 19 per cent of those who used 1 quart or more daily were from 12 to 15 years of age, but 29 per cent of those using less than 1 quart daily were in this age group.

Physical Defects and Gain in Weight—An analysis of the records sorted and sub-sorted on the basis of the presence or absence of diseased tonsils, dental caries, defective vision, and nasal obstructions, revealed no significant differences in gains in weight during the semester in which the defects were corrected. Hence, the presence of varying proportions of these physical defects in the milk groups could not account for variations in the gains found in the different groups based on milk consumption.

Family Finances and Gain in Weight—The financial status of the family, good, fair, or poor, as reported by the nurses showed no significant relationship to gains in weight. The average semester gain per pupil for children from families with good incomes was only 0.18 lb. greater than that for children from families with poor incomes.

In both years covered by the investigation relatively more children from families with low incomes received no milk than children from families with moderate or high incomes, and conversely, a smaller proportion of children from families with low incomes received

milk at home and at school than children from families with moderate or high incomes.

Home Food and Gain in Weight—Further analysis of the records suggest that the use of what is generally recognized to be sufficient milk is more essential for children in families with low incomes having poor food than for children in families with favorable incomes having adequate food. In the well-to-do families where plenty of food of variety is available the addition of milk may contribute less to a well balanced diet than it does to the diet of families in economic stress.

A suggested relation of the adequacy of home food to gains when the Sherman standard of not less than 1 quart of milk daily is observed, is shown in Table III. The differences in gains were found to be too small relatively to the probable errors to be regarded as highly significant, but the consistent results of the various groups appear reasonable. In the vertical comparison in this table, with "Sufficient milk" the gains were 8 per cent greater when home food was rated by the nurses as "good," rather than "poor"; with "Insufficient milk," however, the increased gain with good instead of poor food was much greater, 19 per cent. It appears that good food was more important when pupils received insufficient milk.

Likewise, sufficient milk was more essential when children had otherwise poor home food. In the horizontal comparison in Table III, with poor food those getting sufficient milk gained 20 per cent more (4.09 lb. compared with 3.40 lb.) than those getting insufficient milk, while with good food those with sufficient milk gained only 9 per cent more (4.41 lb. compared with 4.06 lb.).

Home Rest Period and Gain in Weight—Pupils reported to have good rest periods at home daily made

GAINS IN WEIGHT MADE BY 425 UNDERNOURISHED PUPILS WHO USED DIFFERENT AMOUNTS OF MILK WHEN OTHER FOODS WERE CLASSED AS GOOD, FAIR AND POOR
Health Instruction Groups, Division of Medical Inspection,
Philadelphia Public Schools—1931-1932

| <i>Home Food</i> | <i>Gains in Weight When Each Pupil Used Less Than One Quart of Milk Daily— "Insufficient Milk"</i> | | <i>One Quart of Milk or More Daily— "Sufficient Milk"</i> | |
|------------------|--|-------------------|---|-------------------|
| | <i>Pounds</i> | <i>Per Cent *</i> | <i>Pounds</i> | <i>Per Cent †</i> |
| Poor | 3.40 | 100 | 4.09 | 100 |
| Fair | 4.02 | 118 | 4.26 | 104 |
| Good | 4.06 | 119 | 4.41 | 103 |

* Taking 3.40 lb. as a basis for comparison

† Taking 4.09 lb. as a basis for comparison

greater gains than those having poor rest periods. When the milk drinking factor was held constant by sub-sorting, it was found that of the 440 children in the group classed as "Milk at school, no record of home use," 157 children had a fairly satisfactory rest period and gained 4.04 lb. per semester compared with a gain of only 3.02 lb. made by the 283 children whose rest period was reported as unsatisfactory.* This is a significantly greater gain and argues for an adequate rest period at home.

Finally, it has been the aim of this section of the paper not to discuss the relative merits of the weighing of school children as an index of nutrition or to establish the thesis that the use of milk causes increased gains in weight, but rather to show that gains in the weights of the undernourished children whose records were studied were positively associated with the use of milk in the diet. It is recognized that gain in weight may be an inadequate index of progress toward normal nutrition and that a cause-effect relationship cannot be proved by statistics. The writer is

in agreement with Whitney, who writes⁶:

We know that growth depends on many factors. We cannot separate these scientifically and specify exactly the factor that is responsible for each separate unit of growth. Therefore, to teach children that there will be an increase in weight or height immediately following increased consumption of milk is misleading and creates by its exaggeration a false idea in the child's mind. Yet it is valuable for children to realize that milk is an important food in the diet of growing children, and this true idea can be given children effectively without leading them to expect results which no one can guarantee.

USE OF MILK AND SCHOLASTIC PROGRESS

Reports of the scholastic progress of a majority of the pupils enrolled in the special health instruction classes were obtained from the teachers. The relative merits of the combined judgment of teachers in comparison with objective tests is not within the scope of this paper. There is here presented only a brief statement of the relationships of the use of milk and scholastic progress as disclosed by existing records. It is not conclusive, but indicative of existing tendencies.

For the 2-year period, 45 per cent of the pupils receiving milk were shown to have improved in scholarship, while improvement was recorded in only 24

* All the sub-sorts on the basis of the use of milk showed similar results. Approximately the same proportion of pupils having unsatisfactory rest periods were found in each milk-use group, and therefore this factor did not change the relationships between the various milk groups.

per cent of the cases in which milk was not used. It is of interest to note that a higher percentage (56) of those who received milk at school were reported to have improved in scholarship than was found for the other groups.

These observations relative to the use of milk and scholastic progress parallel results in the studies made under the direction of the Scottish Board of Health⁴ when milk was given as a supplementary food in school. Editorial comment on the Scottish report reads⁷:

The improvement in the general health was such that the groups of children receiving milk could be picked out merely by inspection. The good effects of adding milk to the diet were, indeed, even more obvious in the period covered by this second report than they were in the previous period, and it was significant that the improvement was mental as well as physical. Dr. C. A. Douglas says that "general alertness was common to all the children fed on milk."

There is much evidence of the association of physical fitness and scholastic progress. Cornell has presented statistical evidence covering work in 4 schools⁸ showing:

In each school, and in each individual branch of study in each school, the healthy or normal children stood higher in their classes than the average children, and the physical defectives, taken as a class, stood lower than the average children.

Scientific evidence supports the conclusion that a well developed, disease-free, and properly nourished body

furnishes the most favorable environment for the highest development of the natural mental equipment. While one's maximum mental capacity may not be actually increased, the existing mental equipment may be made to function more satisfactorily when physical handicaps are removed and the body is properly nourished.

Fumigation of Foodstuffs*

Public Health Aspects of an Increasing Commercial Practice

C. L. WILLIAMS, M.D.

Senior Surgeon, U. S. Public Health Service, Rosebank, Staten Island, N. Y.

THE fumigation of foodstuffs has reached proportions that render it imperative that we take specific notice of its effect on the public health. Available data do not permit of precise statements, but from figures furnished by manufacturers of fumigants it is estimated that during the year 1931 there were fumigated in the United States 700,000,000 cu. ft. of building space (mostly warehouses, flour mills, etc., containing foods), 500,000,000 lb. of commodities (mostly foods, in fumigation chambers), 4,000 ships (many of them loaded), and 7,000 railway freight cars (loaded and empty). These figures are conservative. The practice is growing, so that it is believed the figures for 1932, when compiled, will be larger by from 10 to 25 per cent.

Purposes of Fumigation—Except for the destruction of rats on ships, there is hardly any direct or specific public health purpose involved in fumigation. It is employed almost exclusively to destroy vermin that for one reason or another constitute an economic loss; largely, this is the destruction of various insects infesting foods.

Fumigation Processes—There are two principal processes: (1) fumigation at atmospheric pressure, (2) in a vacuum chamber.

The vacuum process insures penetra-

tion of the fumigant into practically any package that can be put into the apparatus; the treated material may absorb as much as 80 per cent or 90 per cent of the gas. When fumigation is at atmospheric pressure, much smaller proportions are taken up, while penetration into different types of materials varies greatly and requires much longer time.

Materials Used—There are quite a number of fumigants used in commercial practice, but only a few to any considerable extent, these being hydrocyanic acid, cyanogen chloride, sulphur dioxide, carbon bisulphide, ethylene oxide, ethylene dichloride, and chloropicrin. All of these are gases at ordinary temperatures or are converted to gases by simple evaporation; all are poisonous, in some degree, to all forms of animal life; all are absorbed to some extent by the materials fumigated. Continued aeration will remove the greater part of the absorbed gases, but there is considerable variation as to the time required.

The varying toxicity and speed of action of these gases is reflected in the varying concentrations and periods of exposure employed. In commercial practice, these factors tend to balance one another, the more toxic and quickly acting materials being used in smaller amounts and for shorter periods.

Absorbed Gas—The hazard peculiar to the treatment of foodstuffs is the

* Read before the Food and Nutrition Section of the American Public Health Association at the Sixty-first Annual Meeting in Washington, D. C., October 25, 1932.

absorption of gas in the fumigated material. This has been known for years, but the subsequent effect on consumers has never been completely and authoritatively determined. While hydrocyanic acid, because of its high toxicity, naturally has attracted attention, other fumigants have not been so closely studied. The thought has appeared that if HCN may be safely used, other materials of lesser toxicity are harmless. This may not be true; other gases must be used in heavier concentrations, and their mechanism of poisoning is different.

Absorption of fumigants is dependent on quite a number of factors, the most important being the process, concentration of gas, length of exposure, temperature, and the presence of moisture. Fats absorb larger amounts of those that are fat solvents. Porosity increases the speed of absorption. All of these also affect the rate of subsequent dissipation.

Three things may happen to gas absorbed in foodstuffs: the gas may be retained in its original form; it may be given off when the food is removed into fresh air; or it may become chemically combined with the ingredients of the food. As regards the first and second possibilities, the status at any one moment is a matter of time. When fumigated foods are removed into the open air, the absorbed material immediately starts to pass into the air and eventually all that is in a free state will be so dissipated. While it has been noted in some cases that the fumigant combines with certain foods, hydrocyanic acid with levulose and ethylene oxide with water being demonstrated instances, the data at hand indicate that in practice this occurs only to a quite limited extent.

Absorption Studies—The problem of absorbed fumigants has been studied principally by chemical methods. Studies have usually been carried out

by exposing samples of foods to varying amounts of the fumigant for varying periods, and determining at intervals thereafter the amounts of gas remaining in portions of the sample. This method would have supplied us long ago with a definite answer to the problem were it not for the failure to determine whether the fumigant found in fumigated foods was actually poisonous when consumed. In the few instances where such tests were made, no poisoning could be detected. Most of these are concerned with foods that actually absorbed or retained relatively small proportions of the fumigant.

Absorption Hazards—The fumigant absorbed in foodstuffs may become a hazard in two ways. If stored in a closed space, evolution of the absorbed gas may produce a lethal or toxic concentration in the air of the storage chamber. This is a danger that is often given entirely too little thought, though it is far more real than the other hazard, that is, poisoning of consumers by retained gas. So far as published data go, there have been a number of fatalities from gas released from fumigated materials, but there is no instance on record, of which the writer is aware, of any human being ever having been killed by eating fumigated food.

The absence from the literature of any report of death from consuming fumigated foods is remarkable and deserves particular emphasis. Quite a number of writers have given their attention to this subject; so there has been no lack of search. The only reasonable conclusion is that no such deaths have occurred.

Evolution of gas in storage is a hazard that is not peculiar to foods and so will not be further considered here.

The presence of any considerable amount of absorbed fumigant can be detected by smell or taste, particularly (due to evolution of the gas) the former. Trained fumigators find the

sense of smell a reliable test, the practical experience of years bearing out the belief that when the odor of a fumigant has disappeared, the amount still retained is small.

Hydrocyanic Acid—Because hydrocyanic acid is the fumigant that has given rise to the most concern, it is advisable to discuss it in more detail.

The effect of hydrocyanic acid fumigation on foodstuffs was recently investigated and the data at hand reviewed by Monier-Williams¹ for the International Commission on Fumigation of Ships, sponsored by the League of Nations and the Office International d'Hygiène Publique.

Largely because of the lack of data as to actual poisoning by absorbed HCN, Monier-Williams was quite conservative in drawing conclusions as to the permissible content in foods. The Commission, in its report,² was equally conservative, stating that 20 p.p.m. HCN in food probably does not affect the health of the consumer. As a matter of fact, considerably larger amounts than this have undoubtedly been consumed on numerous occasions without any effect whatever being noted.

The German and French regulations permit the importation of Rangoon beans containing as much as 300 p.p.m. of HCN. These regulations, however, take into consideration the fact that the beans are cooked before consumption.

For many years, it has been a common practice for fumigators to eat food immediately after fumigation; in fact, on ships, the writer has known fumigators (protected by gas masks) to go into compartments under fumigation and bring out food to be immediately consumed. In such cases, however, the concentration of gas used was not high—seldom over 0.2 volume per cent of HCN. However, Moore³ reports instances of fumigators consuming candies and nut-meats fumigated in a much

higher HCN concentration—1 volume per cent—within a few minutes of their removal from the fumigation chamber, without any signs of poisoning being noted. The writer has frequently eaten fumigated foods within a few minutes of their removal from the gas, and has noted that in the dry foods such as crackers there was no taste of HCN, but that sometimes in fruits such as grapes and apples the gas could be detected, presumably more through odor than taste. Fruits that were eaten after peeling showed no signs of gas.

The relatively few animal tests have all been negative. Some years ago, the U. S. Public Health Service⁴ fumigated bread and milk with gas concentrations up to 0.4 volume per cent, and fed it to mice—in some instances immediately after fumigation, and in others after a period of airing. The conclusions were that in no cases were the mice affected by eating the food, but in some instances when placed in jars with unaired fumigated food, they were killed by breathing the gas evolved.

Swanson and Working⁵ cite experiments wherein fumigated grain was fed chickens. In nearly all of these cases, the grain contained about 20 p.p.m. of HCN and was fed to the test animals over periods of several days to 2 or 3 weeks. In no instance could any poisonous effect be noted. Buitenberg and Weiss⁶ fed fumigated foods containing from 10 to 30 p.p.m. of HCN to men in place of their regular diet, over periods up to 1 week, without noticeable effect. Lutrario⁷ fed fumigated food containing 20 to 100 p.p.m. of HCN to dogs, in approximately 500 gm. portions, without effect. Other instances might be cited, but they are all of the same order.

As against these data we have a considerable volume of chemical determinations which have shown that the amount of HCN absorbed varies very considerably. In some instances, im-

mediately after fumigation as much as 2,000 p.p.m. were found. While this was exceptional, it has not been unusual to find as much as 100 or even 200 p.p.m.

More than 100 p.p.m. appear practically only in foods fumigated by the vacuum process or, at atmospheric pressure, with concentration of the gas greater than the usual limit of 1 volume per cent. In the former case, it is usual commercial practice to air-wash, in the vacuum chamber, goods designed for shipment within a short period. When fumigated foods are cooked prior to being eaten, retained hydrocyanic acid is reduced to a negligible figure, the high temperature causing it to be rapidly dissipated.

The fatal dose of hydrocyanic acid is generally placed at 60 mg. It will be seen, therefore, that when a food contains 100 p.p.m., it would be necessary to consume 600 gm. of it to ingest a fatal dose of the poison. This amount is a rather large portion of any one food.

Hydrocyanic acid inhibits the consumption of oxygen by the tissue cells. The poison is in part removed by conversion in the body into less toxic substances and in part by elimination, most rapidly through the lungs. Its inhibitory action on oxygen consumption depends largely on the concentration present, so that toxic action is measured by the balance between the rates of absorption on one side and of chemical change and elimination on the other. It will be appreciated, therefore, that poisoning by way of the stomach is dependent more on the rate of absorption than on the total amount of HCN ingested. An amount, poisonous when taken in concentrated form, might be totally innocuous when mixed with a large quantity of food. Furthermore, if the food contains sugars, a still larger amount of HCN may be taken with it, it having been shown that

sugars eaten with or shortly before consumption of HCN definitely reduce its poisoning effect.

According to data at present at hand, only small amounts of HCN are fixed in foods by combination with levulose, hence, its removal from fumigated foods is relatively complete if sufficient airing is permitted. As a rule, 24 hours' ventilation gives a safe margin. The potential menace is the factor of the time between completion of the fumigation and consumption of the food. Consideration of this factor at once removes certain fumigations altogether from the dangerous list. Prominent among these are fumigations of grain in storage, of flour mills, and of practically all foodstuffs at the place of manufacture.

When we go to fumigations of foods at the point of sale, however, the time interval before consumption is much shorter. For example, the fumigation of a grocery store on a Sunday may be followed by sale of some of the stock next morning.

A still shorter interval would occur when a dwelling is fumigated without removal of the household food stores and a meal is prepared from these immediately after the family is readmitted to the premises. While it would appear, from some chemical determinations, that such practice might be dangerous, no instances of actual poisoning have been reported.

Ethylene Oxide—During the past few years, ethylene oxide has come into considerable favor as a fumigant for foodstuffs. Being necessarily used in much heavier concentration than HCN, more of it is absorbed, but this increase is balanced by its much lower toxicity.

Ethylene oxide is stated to have a narcotic action. It is known to be locally irritant to the stomach and lungs, and probably to other tissues. In the presence of water it forms, at

ordinary temperatures, a limited amount of ethylene glycol, which in the body is in part oxidized to oxalic acid, a well known poison. As in the case of HCN, however, it has been clearly shown that the minimum poisonous dose is in excess of the amount retained in foods, either as the unchanged gas or as ethylene glycol. In the first place, the retention of about 5,000 p.p.m. would be necessary to include a poisonous dose in a 500-gm. portion of food, while to be poisoned by the ethylene glycol that might be formed, a man, on the basis of any reasonable computation,⁸ would have to consume some hundred pounds of the fumigated food at one sitting. According to Schwartz and Deckert,⁹ 90 per cent of absorbed ethylene oxide is removed by 24 hours' aeration.

Other Fumigants—What has been stated with regard to hydrocyanic acid and ethylene oxide applies in general to the absorption and subsequent health menace of other fumigating gases. Space does not permit an account of all of the fumigants mentioned, but it may be stated for all fumigants now in general use that there exist no specific data to support any contention that these absorbed in fumigated materials are a menace to consumers. While the volume of fumigation of foodstuffs is high, report of morbidity or mortality from the consumption of fumigated foods to date is zero.

New Fumigants—In view of the statement just made, it is well here to sound a warning. Chemical progress is constantly supplying us with new compounds, and it is to be expected that new fumigants will appear from time to time. What changes they may produce when used to fumigate foodstuffs can be determined in each instance only by careful investigation, which should always precede their introduction into general use.

Moist Foods—Chemical study has shown that many of the fumigants,

notably hydrocyanic acid, are absorbed in considerable amounts by water. In consequence, it is not advisable to fumigate moist or liquid foods that would be consumed shortly thereafter. For example, in the fumigation of a restaurant, it is wise to remove all milk, milk products, butter, and any other liquid or quite moist food that would likely be consumed shortly after fumigation, particularly foods that would not first be heated.

Chronic or Cumulative Poisoning—The possibility of chronic or cumulative poisoning from the frequent ingestion of foods in which small amounts of fumigant gases may be retained has not been stressed—(1) because there are very few data at hand relative to the possibility of its occurrence, and, (2) because the proportion of foods at present fumigated is too small to render it at all likely that any one would receive fumigated foods at frequent intervals. We may come to the day when most of our foods will be fumigated, by which time it is quite likely that this question will have been answered.

CONCLUSION

While one prefers to base definite statements on careful scientific determinations, yet it is not proper that we ignore practical experience when it all points in the same direction and its volume is sufficient to cover adequately variable circumstances. Fumigation of foods has been practiced for a generation. The aggregate volume of fumigated foods is large; yet no one has pointed to a single instance of death or even illness among the consumers. It would seem, therefore, to be a safe conclusion that fumigation of foodstuffs does not constitute a public health menace.

So convincing is the large volume of negative evidence that the Surgeon General of the Public Health Service felt

justified, in 1930, in stating: "This Bureau is not acquainted with any evidence of harm to human beings from the use of food products that have been treated by the cyanide method. . . . It seems that the experience of many years, covering the use of this material, furnishes us with better evidence of harmlessness than would be secured by much experimental work."

While there is not the same volume of data as regards other fumigants, all to date point to a similar conclusion.

As a control of foodstuff fumigation, there would appear to be but one regulation reasonably justifiable—that after fumigation, foodstuffs, before consumption, sale or shipment, should be ventilated not less than 24 hours and until the fumigant is no longer detectable by taste or smell.

Maternal and Child Health Work Under Social Insurance in France

A RECENT report on the working of the French social insurance law of 1930 points out the health work for mothers and children performed under that law. The insured woman and the non-insured wife and children of the insured man receive in case of illness medical attendance either at home or in an institution. Financial assistance is given to the insured woman when she is in need of preventive treatment and able to do only part-time work. Complete physical examinations are provided free of charge at certain intervals to all insured persons.

The insured women and wives of insured men are entitled to free medical attendance during pregnancy and for 6 months after the birth of the child. The insurance fund also pays a certain part of the expenses incidental to childbirth, or 6 weeks before and 6 weeks

after childbirth the insured woman receives a daily cash benefit on condition that she abstain from paid employment. A nursing benefit is also paid to her for 9 months. The women in receipt of benefits are required to present themselves and their babies at the health centers at certain intervals. They are also visited by public health nurses.

The insurance organizations are permitted by law to give a part of their reserves to various health agencies, such as health centers for mothers and children, maternity homes, sanitariums, rest homes, clinics, and others, or to establish such agencies themselves. In a large number of cities the insurance organizations which do not have their own health agencies have made arrangements with other such agencies for the care of their mothers and children.—*Paris Médical*, March 18, 1933.

Precaution When Filing Deferred Certificates*

STEWART G. THOMPSON, D.P.H., F.A.P.H.A.

Director Bureau of Vital Statistics, State Board of Health, Jacksonville, Fla.

AMONG the problems facing us today, there is a series of irregularities in connection with the filing of deferred certificates. Efforts to put on file a false date of birth have been repeated in so many instances that it has caused at least one of our government officials to apply the term "racket" to the systematic, well planned efforts to evade the requirements of law. The value and importance of a birth certificate have been so widely accepted that it is difficult to realize that a channel is left open for falsifying records in cases where considerable time has elapsed between the date of birth and the filing of the certificate, enabling the interested party to claim citizenship, government compensation, inheritance rights, etc., to which he is not entitled. States authorizing the acceptance of birth records many years after the date of birth are assuming a grave responsibility and, unless each individual case is carefully safeguarded against the many known forms of irregular testimony, there will be a tendency to blight the cause of registration and lower the standard of the regular records.

It is not just a theory that there is danger of fraud in connection with the filing of deferred certificates. For example, one doctor in particular signed a birth certificate for a birth which he did

not attend. When this was discovered, his explanation was that he did not attend the birth but that the certificate was signed as an accommodation to the patient. Attempts have been made fraudulently to change the names on birth certificates. Investigation revealed in one instance that the certificate in question had been filed properly but that an individual from a foreign country, wishing admittance into the United States, endeavored to use the certificate as his own by having his name inserted. This would not only cause the falsification of a legal record but would, in addition, ruin and obliterate a true and correct certificate which might at a later time be required. Another case which has come to light is that of an old midwife who signed three birth certificates, swearing to attendance and to the fact and date of birth. The immigration officials found the records to be false and, of course, deported the individuals who were in this country endeavoring to use the fraudulent records. The problem under discussion affects more keenly the states having new laws. After a few years of registration, when certified copies as evidence are required more often, its importance is realized. Then, individuals born prior to the enactment of the law make efforts to have their births recorded and the registrar's troubles begin.

In filing a certificate to be used in applying for a passport, there is very often carelessness or lack of true in-

formation as to the exact date of birth, which results in a false record. Later, this same record may be needed when an inheritance proof is desired and, though the record could be used in securing a passport, it will not serve in connection with the inheritance. Carelessness in tracing down exact information very often results disastrously to those affected.
